About the Guide

The *Computerworld Buyer's Guide to Software* is a reference manual containing concise descriptions of software products and short profiles of the vendors selling these products. Software products included in this guide are for both large systems and microcomputers.

The guide has four major product sections — applications software, system software, data base management systems and utility software.

Product listing sections are preceded by a divider, with a fold-out tab identifying the products listed within that section. Applications software products, which account for approximately one-half of the products listed in this guide, are contained within three tab dividers entitled: Accounting (Section A), Manufacturing, Banking and Insurance (Section B); and Payroll/Personnel, Word Processing/Text Editing and Other (Section C). The remaining product listings are contained within three tab dividers entitled: System Software (Section D), Data Base Management Systems (Section E); and Utility Software and Applications Development Systems (Section F).

In cases where several different types of products are included within one tab section, a grey-colored page with a product classification identifier is inserted before the listings for that particular product grouping.

Preceding the product listings is a vendor profile unit (Section V).

The front of the guide has a magazine section featuring articles about the state of the industry, markets and technical information for specific product categories and issues concerning software.

Also featured in the guide are separate indexes which provide a method for quickly locating the diverse products listed in the guide.

PRODUCT LISTINGS

There are 24 distinct product classifications contained within the *Computerworld Buyer's Guide to Software*. In cases where a product does not fall into one of these categories it is listed in a section entitled "Other". Within each category, vendors are listed alphabetically.

Each product listing contains the package name; the specific application and/or industry for which the product is designed; the hardware and/or operating system on which the product runs; the amount of main memory required; the source language and availability of source code; pricing and installation data.

In some instances, vendors indicated their products were designed for more than one purpose. The secondary usage for these products is denoted by the specification entitled *additional product classification*.

In cases where a vendor's software package operates on both a microcomputer-based and a mainframe or minicomputer system, the product listing will be found in the section containing the listings for the larger system. Those packages designed for small business systems will be found in the listings for microcomputer software.

In an effort to keep this guide to a manageable size, the number of listings of software products offered by major hardware vendors were limited. In general no hardware vendor has more than 25 products listed. The major hardware vendors usually have a directory of their software offerings, which are available upon request to customers and interested parties.

Each vendor's product listing also contains a cross-reference directing the reader to the appropriate page for the vendor's company profile.

An example of a product listing is shown at right.

About the Guide

COMPANY PROFILES The company profile section of the *Computerworld Buyer's Gutde to Software* contains each vendor's address and telephone number as well as a listing of key management, marketing or technical personnel within the firm. In addition, the profile includes the company's target markets, revenue, among other details.

INDEXING SYSTEM Each tab divider contained in this guide has a "Product Locater" index, which is appears at the end of each tab section. The Product Locater gives the name of the package, its price and the page on which the complete listing for the product is found. This facilitates the search for a software package if the reader knows the name of the product, but does not know the vendor of that product.

THE ENTERPRISE FILE The Enterprise File is a data base containing information on the thousands of companies that produce or provide computer-related products and services. It is the source of listing information contained in the *Computerworld Buyer's Guide to Software.*

The project was started in April 1982 and is a complement to the International Data Corp. Data File, a well-known data base of end-user facilities.

Information is gathered and regularly updated by International Data Corp. through printed questionnaires and telephone surveys. To date the Enterprise file has records on nearly 12,000 companies and is targeting 35,000 to 40,000 products for inclusion in the file in the near future.

Note: Vendors were offered the option of placing their company name in a larger typeface than the standard listing size. Vendors were also offered the opportunity to add a boxed insert at the the end of their listing. These options were paid for by the vendors and should in no way be construed as an endorsement of these companies or products by the publishers of the *Computerworld Buyer's Guide to Software.*

Editor's Note

As computers fan out, finding their way onto desks throughout organizations everywhere and as more business functions are automated, the amount of software available to keep these systems humming grows in exponential progression. The *Computerworld Buyer's Guide to Software* reflects that theorem. This guide contains approximately 10,000 products from 3,200 vendors — and that's after weeding out a huge amount of software as well as limiting the listings of products offered by hardware vendors. Approaching the 800-page mark, this guide is certainly the bulkiest of the series which began last August with the *Computerworld Buyer's Guide to Computer Systems*. In fact, it took 14 tractor-trailer truckloads to distribute this issue of the series.

So what does all this proliferation of software mean? One theme the magazine section in this guide reflects is the concern with making computing power available to and easily accessed by managers and professionals in every industry. Articles in the magazine range from end-user computing issues to artificial intelligence, from mainframe-to-microcomputer links to microcomputer data base management sytems and information centers. It appears that end-user computing has come of age.

This year, vendors have certainly been busy bringing products to market for usage by people whose major function is not involved with management information systems (MIS). While many products will not be delivered until sometime next year, the future frontier of software has been charted.

IBM, often criticized for letting small, independent companies take the lead in bringing innovative products to market, has responded to the demand for end user computing. Evidence of this is its introduction of DB2, a relational data base system for its MVS environment; its agreement with Artificial Intelligence Corp. to remarket Intellect, an artificial-intelligence-based product; its introduction of the Personal Computer XT/370 and the 3270-PC, systems that bless the mainframe-to-micro link; and the emergence of Oxycalc, a mainframe-based spreadsheet package.

Likewise, other vendors have not been idly standing by watching the end-user computing parade. Cullinet Software, Inc.'s IDMS/Relational and other personal computer software offerings recognize the importance of the microcomputer to the professionals and managers in organizations. And Applied Data Research, Inc.'s Ideal, an applications development system for both technical and nontechnical users, also emerged during this past year. In addition to these products, Mathematica Products Group, Inc. introduced an "English" front-end for its Ramis II data base management system.

The introduction of new products that make it easier for end users to access corporate data is expanding the universe for software systems. But are MIS professionals ready to greet the new software frontier? The challenge is two-fold; not only are managers of information systems being called upon to evaluate software tools, making sure that they mesh with other corporate systems, but also they are being relied upon to create the environment that will ensure these new products are used efficiently.

A few years ago information processing managers spent a good deal of time worrying about programmer productivity — how to glean added performance from trained information system specialists. Programmer resistance to tools such as fourth-generation languages and prototyping was a topic of heated debate on the conference circuit. In some ways it is ironic that managers and professionals in corporate departments are quickly embracing the very products that were resisted by many information processing professionals who had long been oriented to a procedural approach to developing systems.

On the other hand, this phenomon may indicate that an entirely new environment was necessary to prod computing into taking the next step beyond.

EXPANDING THE UNIVERSE

Many of the newest software products are being designed to allow professionals and managers to access and use corporate data. The following four stories explore these trends and offer insight into the future software environment.

A New Dimension In Software

By Dr. Larry R. Harris

Within the past two years, artificial intelligence (AI) has been propelled out of the research laboratory and into the commercial marketplace. Although there are relatively few AI-based products on the market today, the impact of these products is already being felt. Industry giants such as IBM and Digital Equipment Corp have already begun to incorporate AI into their systems. The Japanese have placed AI at the center of their fifth-generation computer plans. Many others are scrambling to understand what this technology can offer and how it can be integrated into their product lines.

The field of computer science research known as artificial intelligence attempts to simulate human cognitive behavior using a computer. AI techniques rely heavily on symbolic representation and manipulation of data rather than on the number crunching normally associated with computers. By representing information symbolically, AI systems can carry out complex logical operations such as inference, planning, language understanding and so forth. These capabilities allow AI-based systems to perform much higher level tasks than their conventional data processing counterparts. Systems for performing medical diagnosis, minicomputer configuration and language understanding have already been built using AI technology.

The excitement surrounding AI-based products is due to the fact that AI systems allow a whole new class of problems to be solved. It is not that they solve a problem faster or better than it was solved before; in most cases, the problem could not be solved by computers at all. Thus, the promise of AI systems is that they allow entirely new areas of human endeavor to be automated. Furthermore, the improved man-machine interface offered by today's AI systems allows for experts to work with AI systems to address jointly problems that neither alone could solve.

The evaluation of conventional software systems such as data base management systems (DBMS) or applications packages has already evolved a set of procedures to ensure the proper fit between the user's needs and the product's capabilities. Evaluating AI-based software products is an extension of this methodology. But in addition to the normal caveats regarding software selec-

tion, there are two unique aspects of AI based software of which buyers should be aware.

The first is that AI systems address such large and ill-defined problems that they cannot completely solve the problems in all cases. AI systems cannot carve out some neat area of functionality and completely resolve all the issues in that well-defined area. Rather, AI systems address a large problem area that is rarely well-defined, such as a medical diagnosis system, which will not always make the proper diagnosis. There will always be English sentences that an English-understanding system will not understand or scenes that a vision system will misinterpret. Since AI systems cannot solve a big problem in its entirety (remember that not even humans can do that), the burden is on the buyer to assure himself that the degree to which the system solves the problem is sufficient for the user's purpose. This is not always an easy determination to make before buying a system.

The second aspect of evaluating AI software is recognizing that AI software always demonstrates itself in an impressive fashion. This, in addition to the previous point, lays the groundwork for the system to be oversold. Often, the vendor is not solely at fault. Buyers, in their exuberance at seeing AI capabilities being performed, often extrapolate what they saw during the demo to a point well beyond the system's capabilities. Buyers must remember that demonstration problems are always chosen by a vendor because they show a system in its best light.

There are two classical solutions for buyers to employ for both of these problems. One is to check user references for a product. The other is to try a product out before purchasing it to assess its overall performance.

Checking user references for software products is a well-proven technique in evaluating all software products. For the reasons stated above, it is particularly important for AI software. Reference checking is perhaps the easiest way to determine whether a system addresses a sufficient amount of an overall problem. If other users have found a product to be a successful business tool, then the chances are much greater that it will work for you as well. But be careful of references to sites in which a system is in test or under evaluation. These may be signs of a system not being a fully usable tool. What you want to hear is that a system is "in production." If you cannot get a reference to a good production site, you should realize that you will be one of the pioneers in using the product. Someone, of course, has to be the first to put a product in production, but you should seriously consider whether that someone should be you.

After checking user references, the next step is to try the product out before purchase. This, of course, is the only way to be certain whether the product is going to be a useful tool for you. Unfortunately, the degree to which the system must be customized for your application may make the trial an expensive proposition for both you and the vendor.

A good compromise is to install the product on your machine with a demonstration application that is similar to your target application. From this test, you can get accurate performance data in your actual environment and also define the limits of the AI component of the system. This experience with the system will provide a much more accurate assessment of its capabilities than the sales demonstration, since you will be using the system yourself in a unconstrained mode. This information, plus the reference checks, should be sufficient to make the buy or not-to-buy decision.

AI Market Structure

The hierarchy in the diagram on page 12 shows the relationship of the existing AI market segments.

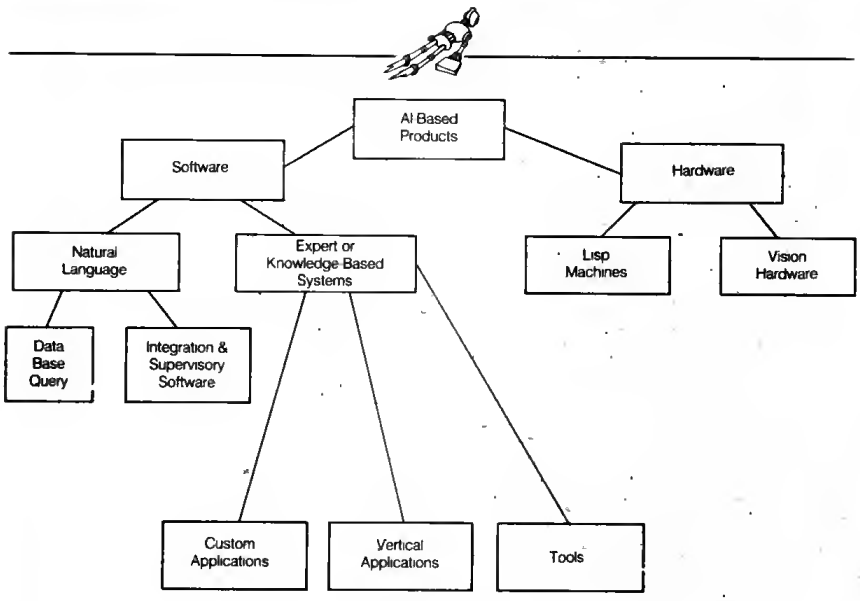
The first portion is software vs. hardware. In essence, all of the AI in any system lies in the software, but some of the application areas are so task-specific, such as vision and robotics, that it is easier to think of these as hardware devices since they are physically embodied in hardware.

Within the commercial software areas, there is the natural-language segment and the expert-systems segment. "Natural language" is a technical term that refers to the languages people speak, for example, English, French and Japanese. These are distinct from formal computer languages, such as Cobol and Fortran. The natural-language segment involves products that allow users to interact in ordinary English with computers.

Expert or knowledge-based systems are application-specific products that automate the way that human experts solve complex problems. These systems solve problems by building up a long chain of reasoning to lead from basic premises to a conclusion. Both the basic premises and the rules of inference that specify how facts can be chained together are defined by human experts. Together, these are known as the knowledge base.

The major market segments in the hardware category are Lisp machines, vision systems and robotics. The last two are relatively self-explanatory. Lisp machines are general-purpose computers that are optimized to run the Lisp programming language, the dominant programming language of AI research. Virtually all AI systems were originally developed in Lisp. As such, Lisp machines are excellent development environments for AI work, as well as delivery vehicles for the finished product.

Natural-language data base query is the first market into which AI products were introduced. Natural-language processing has been one of the classical components of AI research from its earliest days. It was an obvious first step to marry these techniques with existing DBMS technology.



AI Market Structure

In fact, the data base query environment provides a rather unique fit for the existing natural-language technology. Because the DBMS can act as an extensive dictionary of the words that appear in the data base, the natural-language processor has an easier task handling data base queries than it would in other applications, such as understanding newspaper articles.

The marriage with natural language is good from the data base point of view because data base systems have desperately been in need of a delivery vehicle to make the immense amount of data that is stored in today's data bases available to the decision makers for whom they were built. These decision makers do not know, nor do they want to learn, the formal query languages that come with data base systems. Since these managers already know English, natural-language technology provides this all-important delivery vehicle. An example of the differences between these two language types follows

- *Formal Computer Language.* PRINT LNAME, 82-JUL-ACT-SALES, 82-JUL EST-SALES, 82-JUL-ACT-SALES — 82-JUL EST-SALES, (82-JUL ACT-SALES — 82-JUL-EST-SALES) / 82-JUL-ACT-SALES, IF REGION=' NEW ENGLAND' AND 82-YTD-ACT-SALES < 82-QUOTA.

Intellect

As of this writing, there is only one natural-language data base query product actually on the market — the Intellect system from Artificial Intelligence Corp. of Waltham, Mass. In addition, a number of other companies have either announced products or announced plans to build natural-language products: Cognitive Systems, Inc. of New Haven, Conn., which builds custom systems and interfaces to its advisory systems; Frey Associates of Amherst, N.H., which will run on DEC computers; Mathematica Products Group, Inc. of Princeton, N.J., which will interface with its Ramis; and Semantec of Sunnyvale, Calif., which will run on microcomputers.

The current installed base of natural-language query systems consists of the 150 copies of Intellect that have been installed, including versions of the product that have been installed under different trade names by OEMs. These include Cullinet Software, Inc., which markets Intellect as On-Line English, and Information Sciences, which markets Intellect

How to get a computer company to help unclog your applications bottleneck.

Consider this scenario.

Suddenly, all your management users become able to develop their own special applications. On-line, using their own desktop terminals.

They have immediate access to updated information within their authorized data bases, regardless of where it's entered. They're able to reformat reports and even redefine parameters. Themselves.

You're still very much in control of things, but not burdened by detail. You're free to manage the on-going workload. And the major applications.

It could all happen with the Sperry MAPPER™ System. Not quite "suddenly", but in very short order.

MAPPER is that powerful. Simply stated, it's the most advanced information management tool yet developed.

A tall claim, to be sure. But we're prepared to back it up, conclusively. We'll put MAPPER to work on a real and specific application development problem that a user has given you.

SOMETHING FOR EVERYONE.

MAPPER's simple English-language commands and non-procedural flexibility make it easy for the most computer-shy user to gain proficiency in a day or two. The fact is, MAPPER can be used in all departments of your company and at various levels within the organization. And the MAPPER concept of "user friendly" far transcends anything you've seen.

HERE'S THE OFFER:

Accept our MAPPER Challenge. Bring us an application development project. Bring along the user. We'll show you — without any obligation or cost — how quickly and easily MAPPER gets the job done. It will be an awesome experience for the user. And maybe astonishing even for you.

800-547-8362

But first things first. Have us send you a copy of our brochure, "How to Take the MAPPER Challenge." Call toll-free: 800-547-8362 (9 a.m. to 5 p.m. E.D.T.). Or send us the coupon.

as GRS-Exec. IBM markets versions of Intellect that interface with IBM software, SQL, Vsam and PGF, under the name Intellect.

In the next 18 months, you can expect to see a rapidly increasing number of installations of natural language systems, due primarily to IBM's endorsement of the concept. The rush to introduce these products may compromise the true promise that natural-language systems can deliver. The result will be a few systems that will offer wider and wider functionality of data retrieval, analysis and reporting for the nontechnical end user.

Within the past year, a new use for natural-language technology has become important — the use of natural language as an integrator of other software tools within the information center. This allows nontechnical users to employ data base, graphics, modeling and statistical tools without having to become experts at using each individual system and without having to worry about how data is passed from one system to another.

In this environment, the user interacts with the natural-language component that partitions the work implied by the user's request among the various underlying software tools and then orchestrates the processing and transfer of data from one system to another until the user's request has been satisfied. This may mean taking data out of the human resources applicatinn files under the control of a DBMS, passing it through a statistical filter to summarize it and then passing the resulting data to a graphics system for final display of the result.

In this way, the user makes effective use of four software tools without necessarily even knowing it. This supervisory capability of natural language can leverage the use of the very powerful tools that already exist within the information center. Without this layer of integration, the user is forced to learn several command languages and transfer data across a number of different file formats. Since these tools are nearly always supported by different vendors, there is little consistency from one command language or file format to another. The result is that users end up making use of only one, or at most two, of the tools. The natural-language supervisor delivers the power of the available tools directly to the user.

Over time, more and more tools will fall under the natural-language umbrella, providing information center managers with the ability to customize a natural-language supervisory system for exactly those tools selected as best meeting the unique needs of their users.

Expert Systems

Expert systems simulate the problem-solving capability of human experts in a specific problem domain. For well-chosen problems, the effectiveness of knowledge-based systems can be extremely significant. DEC has stated that the Xcon system for configuration of VAX-11 computers has saved the company in excess of $10 million in its first year of operation. There are undoubtedly similar bottlenecks in almost every corporation that could benefit from this type of automation.

Unfortunately, there is an extreme shortage of "knowledge engineers" — people that construct these expert systems by interviewing human experts and encoding their expertise into the knowledge bases. The worldwide count of knowledge engineers is measured in the hundreds. For this reason, the construction of expert systems is done almost exclusively on a contract basis with a handful of companies that have a sufficient number of trained knowledge engineers.

The primary companies involved in this activity are Smart Systems Technology of McLean, Va., and Teknowledge of Palo Alto, Calif. Each of these companies has a staff of knowledge engineers with a track record of at least successfully building prototype expert systems. Teknowledge has, by far, the largest staff.

In addition, there are a number of start-up consulting companies being formed that claim to build expert systems. Unfortunately, the term "expert system" or even "koowledge-based system" is so loosely defined that it is hard to validate such claims. It is clearly a case in which the buyer must beware, and careful reference checking is strongly advised.

Other successful expert systems used commercially are Prospector from SRI International, which analyzes assay data to locate mineral deposits; Dendral from Stanford, which analyzes mass spectogram data to determine the molecular structure of organic compounds; and the dipmeter adviser of Schlumbeger-Doll, which analyzes oil well log data to determine the presence of the tools.

This segment of the expert system market involves companies specializing in single expert systems that will be of use to all the companies in a specific industry. The analogy to classical vertical applications such as inventory control systems or banking systems should be clear. For example, a company might be formed around an expert system such as DEC's Xcon and sell this capability not only to all the computer manufacturers, but to manufacturers of complex products in other industries.

There are no such vertical expert systems on the market today. However, there has been considerable talk about expert systems being built for the financial community. The likely companies to be involved in this market segment are Applied Expert Systems of Cambridge, Mass.; Cognitive Systems, Inc. of New Haven, Conn.; and Intelligenetics of Palo Alto, Calif.

In the next 18 months, you can expect a number of vertical applications that claim to be expert systems. Many vendors will feel that their existing payroll systems are experts at payroll, but only a few of

Every software ad you read seems to be talking about 'integrated software'. But it was 1-2-3™ from Lotus® that actually gave the phrase real meaning, because we combined spreadsheet, information management and graphic functions in one simple, powerful program.

A program that is faster and easier to use than any other software available today.

In short, the tasks it can perform are really impressive, but why it can perform them is even more important.

Because we feel the real criterion for any management tool is its ability to let the human mind flourish and accomplish more than it ever has before.

That's why with 1-2-3 the thought process is not interrupted, so your mind no longer has to wait for your hands. To the novice, it makes everything plausible. To the expert, it makes anything possible.

The results: Business decisions come faster and easier.

1-2-3 from Lotus is truly compatible with the most important personal computer of all—the human mind.

And isn't that what integration really should mean?

these systems will include any of the AI technology that the name truly implies. But in a sense, it should not matter to the buyer. No one should buy an AI system simply because it contains AI technology. If the AI component does not offer some immediately evident advantages over classical systems, then it does not deserve to be selected.

In addition, there will emerge a handful of true AI-based expert systems that should receive rapid market acceptance once they become sufficiently "bullet-proof" to be cost-effectively installed in a variety of different companies. This process could easily take a couple of years, even after the prototype is complete. For this reason, there will only be a small number of expert-system products in mass distribution in the near future.

Some estimates of the number of trained knowledge engineers put the number at less than 100 in the entire country. Whatever the exact number is, it is clear that it is the limiting factor to the widespread proliferation of expert systems. The expert-systems tools market segment is meant to address this knowledge engineer bottleneck by providing tools to enable companies to build expert system applications with their own personnel.

Essentially, the tools consist of a knowledge-based editor for building and maintaining the knowledge base and an inferencing mechanism for applying the rules. This is the basic shell of an expert system. With several weeks of training, it is hoped that experienced DP personnel would be able to build expert-systems applications with proper use of the tools. The difficult part of the work that remains is the capture and codification of the human expert's knowledge and heuristics in a rule-based form so that the inferencing mechanism can solve problems.

The success of applications built in this way with the standard tools remains to be seen. It seems likely that several types of applications that are of relatively low complexity will be successfully addressed by these tools. Since the financial pay-back is not directly related to the complexity of a problem, some of the applications could have a very large financial impact on the organization. Over time, as the tools and the in-house experience improve, more and more taxing applications will be addressed.

Requirements Distinctions

There is an interesting distinction between the hardware requirements for using the tools to build the expert system and the hardware required to run the production systems. Efficient creation of the application may well require a mainframe or a dedicated high-end Lisp machine. On the other hand, once the application is complete, it may very well be possible to distribute the expert system on a personal computer.

In the near future, a handful of vendors offering tools for expert systems development will emerge. At this point in time, Software Architecture and Engineering, Inc. of Arlington, Va., and Teknowledge have announced plans to provide such a capability.

The Lisp programming language has been the language of choice for AI research for the past 20 years. The AI research centers at MIT, Stanford and Carnegie-Mellon University performed their work almost solely in Lisp in a time-sharing environment on DEC machines. In the late '70s, MIT began developing special-purpose hardware to execute the Lisp language. The result is a high-performance, single-user workstation for Lisp program development. Typically, Lisp machines include high-resolution bit-map graphics and sophisticated mouse-controlled window environments.

The market for Lisp machines is currently for AI research and development centers, but will spread to other environments as applications built to run on the Lisp machines reach the marketplace.

There are currently three companies actively marketing Lisp machine hardware: Lisp Machines, Inc. of Culver City, Calif.; Symbolics, Inc. of Cambridge, Mass.; and Xerox Special Information Systems of Pasadena, Calif.

Another area of AI-based hardware is in vision systems, used mainly for manufacturing quality control. Using AI image-processing techniques, these systems can analyze parts coming down the assembly line and decide whether to accept or reject them. These products tie into the more general area of industrial robots. The vision system can be programmed to interface with a variety of different manipulators to carry out more sophisticated assembly tasks.

The companies currently offering products in this area are Automatix of Burlington, Mass., and Machine Intelligence Corp. of Sunnyvale, Calif. In the next year and a half, we can expect to see more sophisticated vision systems for industrial robots and, perhaps, see some of the AI strategy and planning techniques applied to some of the nonindustrial robots.

The emerging field of commercial artificial intelligence promises a number of exciting entrees into areas that could not, until now, be successfully automated. These new capabilities will undoubtedly have a profound impact on the existing hardware and software markets. The structure of the AI marketplace is defined, and there are a few early entrants in the field. The real impact will be felt as the more established vendors begin integrating AI capability within their existing product lines. In many cases, this has already happened. This process will accelerate as the competitive advantages of AI capabilities become more evident in the marketplace. Thus, the stage is set for AI to take us into what *Business Week* calls "the second computer age."□

STRAIGHT TALK

By Carol Shulman

If you're thinking of acquiring a fourth-generation language, it is probably because you need to reduce dependence on expensive programming expertise, put programming power directly into the hands of end users or reduce the proportion of the budget allocated to maintenance.

These are noble, worthwhile goals, and a fourth-generation language can certainly help achieve them, but the path to using these tools is an obstacle course strewn with pitfalls.

The term "fourth-generation language" has become a buzz phrase. Almost every software vendor claims to offer one. Even the process of identifying which products to evaluate has become a challenge.

The variety of capabilities of these products is

immense, ranging from stand-alone, special-purpose tools to fully integrated products based on data base management systems (DBMS). While buyers have little time to investigate the plethora of products before formulating their requirements, they must be careful not to miss valuable features simply because they don't know they exist.

When evaluating fourth-generation languages, there are four dimensions to consider in deciding how to utilize such a system:

- Who will use it: DP technicians or end users?
- Will it be used to build production applications or to satisfy ad hoc needs?
- Are applications model-oriented or record-oriented?
- Will fourth-generation language products be used on a mainframe, micro or both?

Technicians vs. End Users. There's no need to belabor the obvious importance of this axiom. Suffice it to say that technicians want powerful functionality and will tolerate a less friendly interface to achieve it. Technicians are also well accustomed to procedural languages. End users, by contrast, perform fairly simple tasks. They would rather ask "what" rather than "how" and want the language interface to be as straightforward as possible. Fortunately, most vendors are explicit about the target audience for their product.

Production vs. Ad Hoc Applications. Many fourth-generation languages use more computer resources than standard languages such as Cobol. While this may be fine for a one-time, infrequent or short-lived application, especially if it cuts implementation time by a factor of 10, it may be a problem for production applications requiring heavy throughput or rapid response time. Fortunately, there are fourth-generation languages with Cobol-like operating efficiency.

Model vs. Record Orientation. Modeling is an effective solution for many decision-making problems in finance, marketing and planning. A model typically performs sophisticated operations on a relatively small set of data that is matrix-oriented, usually time-dependent, often a low-volume summary of production data and can be somewhat less current than the production data from which it is drawn.

Fourth-generation languages that support this type of use emphasize rapid construction of a model, provision of statistical and financial routines commonly required for modeling and "what if," goal seeking and simulation capabilities. They often provide only rudimentary facilities for interactive data entry, validation, maintenance and retrieval. Usually, they require the user to describe and store data as a matrix, with time being one matrix dimension. IFPS from Execucom Systems Corp.; Express from Management Decision Systems, Inc.; and Visicorp's Visicalc are well-known members of this genre.

Record-oriented applications, by contrast, typically involve fairly simple operations on a more voluminous set of data. Usually, this data is instance-oriented (one record/instance). It often requires production-system-level detail and may be drawn from several distinct physical files. Production data often has a natural structure that is not easily represented as a single, two-dimensional matrix.

Record-oriented fourth-generation languages usually provide more extensive data entry, validation, maintenance and retrieval capabilities and are far less constrained in the data structures they support. Often, they have much less sophisticated mathematical operators and functions than modeling tools, but more sophisticated sorting, selection and reporting capabilities.

Information Builders, Inc.'s Focus; Nomad, a product from National CSS, Inc., a subsidiary of Dun & Bradstreet; and Ramis, from Mathematica Products Group, Inc., are popular record-oriented fourth-generation languages.

Micro vs. Mainframe. Micros are penetrating the business market. Since most of them are purchased for end users, not technicians, a good fourth-generation language can dramatically increase their usability. While there are far fewer fourth-generation languages for micros than mainframes, they do exist. Some of them operate almost identically on both a mainframe and a micro. Such integration is one of the major trends in fourth-generation language development, for example, IFPS or System W from Comshare, Inc.

Many fourth-generation languages use more computer resources than standard languages such as Cobol. While this may be fine for a one-time, infrequent or short-lived application . . . it may be a problem for production applications requiring heavy throughput or rapid response time.

Until recently, all model-based systems were founded on two-dimensional data structures, one of which was usually time. This structure is adequate for many spreadsheet applications, especially when detailed data is not readily available.

However, as the quantity and detail of data available to the model builder increases — as it has in the past decade due to widespread penetration of computer-based record keeping — n-dimensional (a model consisting of more than two dimensions) capability becomes more and more useful. System W may be the first fourth-generation language to support n-dimensional modeling.

Model-based tools fit well with the following types of applications:

- *Financial Modeling* (pro-forma statement generation, cash

planning, capital budgeting and other spreadsheet-oriented systems).

- *Marketing Analyses* (advertising analysis, product-line sales analysis, buyer-behavior modeling and sales forecasting).
- *Business Planning* (econometric modeling).

Among record-oriented products, a trade-off must often be made between ease of use and execution efficiency, although this distinction is blurring. Still, many tools that yield Cobol-like operating efficiency are procedural and somewhat less friendly than their end-user oriented, nonprocedural, but less efficient counterparts.

Record-oriented fourth-generation languages usually provide more extensive data entry, validation, maintenance and retrieval capabilities and are far less constrained in the data structures they support.

This trade-off tends to mean that the more machine-efficient products are best used by programmers as substitutes for Cobol and other formal languages and for creating production applications. The friendly tools are more appropriate for end users to satisfy ad hoc needs without any programming at all. However, before accepting this standard division of labor, it is important to consider the following points:

- People are getting progressively more expensive than hardware. End-user-oriented tools may reduce programming and maintenance time enough to make the labor savings worth the extra machine cost for some production applications created by technicians.
- Great strides have been made in achieving machine efficiency and high ease of use in a single package. Particularly promising are application generators that automatically generate code with the efficiency of Cobol from high-level, nonprocedural, language-independent specifications.

To understand the total savings fully, any fourth-generation language should be evaluated for its impact on both human resource costs for development and maintenance and machine operating costs.

Most systems for end users are query-oriented. They differ primarily in the complexity of their functionality. Simple query tools tend to:

- Restrict inquiry to one record type at a time.
- Have limited data entry and update facilities.
- Have limited calculation power (they are limited to minimum, maximum, average, sum and so forth).
- Have limited control over output formats.

By contrast, the complex query systems often permit inquiry across several record types, with complex selection criteria. In the best products, the navigation from type to type is transparent to the user.

These products have sophisticated data entry and update facilities, including the ability to use files maintained outside the product's auspices; have calculation power approaching a modeling tool, with built-in statistical and financial routines; and include both a default, a simple display mechanism, a full-fledged, flexible report writer and graphics capability.

Of course, increased sophistication has a price. The complex packages cost more and are harder to learn.

Both kinds of tools are usually nonprocedural, that is, the user specifies what is desired, not how to produce it. They are usually interpretive, rather than compiled. These two factors account for their machine inefficiency relative to production-oriented systems.

Production-oriented tools are often procedural and usually produce compiled code. Many of these fourth-generation languages are outgrowths of DBMS products that began life as host-language calls (interfaces). Later, a higher-level, self-contained language was added to improve programmer productivity.

Many entries in this category have expanded further, adding ad hoc inquiry, modeling capability and graphics output. Each of these features is available for separate purchase but integrate fully with other products to form a "suite" centered around the original DBMS.

Because they began life as DBMS, products in this category are stronger in data entry, validation and maintenance than those in any other category. They have the features automatically expected in a DBMS, such as the ability to define subschemas, specify security, provide for logging, restart and recovery and so forth.

Stand-alone application generators are non-DBMS, production-oriented products. They can usually operate against a number of file structures, that is, those they build themselves, Isam, Vsam, IMS data bases and others. They often generate Cobol or other language code that may then be modified as desired, compiled and loaded.

These products are often screen-oriented. An application is viewed as a menu, and each menu entry has an associated screen that is specified by actually drawing it on the screen. Nonprocedural information is added, such as field security, validation and derivation algorithms, and finally, any procedures associated with the screen, such as file retrieval or writing, are added.

The fourth-generation language automatically codes programs to present menus, parse and route user selections, call up and fill in screens and perform associated processing. Examples in this class include Mark V from Informatics General Corp. and Programmer from Pansophic Systems, Inc.

Several DBMS-based suites have

Perfect for businesses that want to get into computers in a small way.

The Wang VS 25 is the only small business computer that doesn't stay small. Which makes it perfect for small business.

It can meet your data and word processing needs now. And when the time comes to expand, it can expand right along with your business.

A simple upgrading procedure will turn a Wang VS 25 computer into a VS 45, with more storage capacity and twice as many workstations. Later on, it can become part of a larger VS computer network.

What's more, you'll never lose your original investment in peripheral equipment or operator training. Because the VS 25 and VS 45 are completely compatible with a whole family of Wang VS computers. As well as thousands of popular software packages.

This unique growth path makes Wang the only reasonable choice for businesses on the road to bigger things.

No matter how small they start.

recently incorporated application generators that produce code compatible with the DBMS component of the product family. This facility is intended to further improve technician productivity in creating and maintaining production data base applications. Examples include Ideal from Applied Data Research, Inc. and Natural from Software AG.

Here are the important trends in fourth-generation languages:

- Movement away from simple query toward complex query.
- Increased emphasis on interactive applications.
- Movement away from standalone, single-purpose tools toward integrated, multifunction packages.
- Increased ability to access many kinds of files.
- Increased operating efficiency without sacrificing ease of use.
- Provision of compatible products on both mainframes and micros.
- Increased emphasis on nonprocedural languages.
- Integration with word processing.
- Increased emphasis on use by nonprogrammers.

Any specific product is likely to be ahead in some of these capabilities and behind in others. This suggests that buyers investigate a vendor's enhancement history to plan part of their selection process.

There is no set answer, but the following list of features should be considered in addition to those already discussed.

1. Operating Environment. What hardware will it run on? Under what operating system? What are the core requirements? Is batch and/or interactive execution needed? (Hint: Don't buy a batch-only product.) What devices will it support? (Hint: Full screen and graphics support are usually desirable.) How efficient will it be in execution?

2. Interfaces. Can the fourth-generation language call routines in other languages? Can other languages call the fourth-generation language? Can it access external files? (This is a must if it is to be used against existing data.) Can it access files maintained by your DBMS?

3. Data Structures. How does the user see the data: as a hierarchy, network, series of tables/files or a matrix? Is navigation automatic? What about the physical structure? What types of access (such as sequential, indexed) are supported? What data types are supported? How easy is it to reorganize data without changing programs? Will it support textual data, such as memos or reports? Can new structures be created dynamically?

4. I/O. What data entry, validation and derivation facilities are supported? Are default-reports provided? A true report writer? Graphics? Textual formatting? Complex or simple queries? Automatic data base navigation?

5. Analysis Support. How complex can sorting and selection be? What functions are built-in? Statistical? Financial? Simulation?

6. Procedure Support. Can the user define procedures for repeated execution? Can these be parameter-driven? What logic control is provided — such as if-then-else, while-do? Can menus be defined? Screens? Are procedures interpreted or compiled?

7. Human Factors. Who is the intended user? What skills are presumed? What is the learning curve? Does it provide both novice and expert modes? How good is the documentation, including Help and error messages? Is the interface via commands, menus, English-like or mnemonic? Is the syntax consistent, including abbreviation rules? Is it procedural (how) or nonprocedural (what)? How well do these features match the user population? What magnitude of productivity increase has it proven to provide? (Do not underestimate the importance of good human factors in the success of fourth-generation languages.)

8. Vendor Credentials. What support is provided? How many are installed? What is the vendor's record on enhancements — does the company keep up with the times? Will it be there next year? In five years?

Although this list is by no means complete, it should be a caveat that there is a lot to consider before buying o

Staging The Micro To Mainframe Link

By John King III

None of the differences between personal computers and mainframes would have mattered if the personal computer had stayed where computer vendors originally thought it belonged — in the home. But spreadsheets were invented, and personal computers found their way to the desk tops of professionals and managers, making it inevitable that these disparate types of computers would have to be connected. Now it is generally believed that these two types of systems must not only be connected, but must also work together as part of a total system.

Mainframe computers are large, expensive and complex. The complexity is necessary to allow them to serve concurrently many tasks and users. Most manufacturers' computers — even individual computer families from a single manufacturer — support a unique family of end-user terminals with their own character codes, line protocols and physical interfaces. What standards that do exist are de facto only. Each operating system and application software package also has its own format for handling dialogues with end users at terminals.

When compared with large mainframes, personal computers are simple for one reason: They have been designed to support only one user. Designers did not have to follow any standards related to large mainframe computers. The result is a variety of new

microcomputer operating systems, new terminal/screen dialogues and new data base formats.

Distributed processing was a wonderful concept, but it has not yet achieved its full potential because of the lack of software products for integrating different types of computers into complete systems. With personal computers, the problem is further aggravated because original hardware and software concepts were not designed for interconnection. The truth is that most microcomputer vendors, both large and small firms, never viewed their systems as anything other than stand-alone systems.

Major vendors of personal computer products are scrambling to add hardware and software capabilities that will allow their personal computers to interact easily with large CPUs. This effort is now beginning to have a major impact on the market. IBM is following the lead of smaller, more independent vendors and giving the Personal Computer a range of communications abilities. The challenge will now be for independent vendors to keep up with IBM.

For instance, IBM recently announced the capability for the Personal Computer to emulate the 3278 and 3279 display stations. With a special adapter, the Personal Computer can attach via coaxial cable to an IBM 3274 cluster controller. Previously this type of adapter was available only from smaller companies such as TAC and CXI. IBM goes one step further and provides software for file transfer to and from a host CPU. Based on recent public statements by its executives, Apple Computer, Inc. is expected to make a similar 3278-type capability available for its personal computers in the near future.

Because an integrated system is what users need to develop, it is impossible to attack the problem from one end only. Mainframe software and personal computer software must be developed in tandem so that they work together to achieve the user's desires.

What are the various pieces of hardware or software that must be in place to allow such an integrated, distributed system? The first requirement is for a physical interconnection. This means that the host computer and the personal computer must both have the hardware for communications as well as the software to drive that hardware. The connection can be through a remote communications facility using serial interfaces, modems and terminal-emulation software in the personal computer. Alternatively, a local-area network could be used to interconnect several personal computers.

The hardware to allow connections between micros and mainframes is already available from a variety of vendors . There is also a plethora of local-area network products, and most vendors have boards that permit serial communications through external modems.

But the physical connection is the easy part. The difficulty lies in the communications software. Should the personal computer perform like a simple Ascii glass teletype or like an IBM 3270? Should it perform like another manufacturer's terminal, or should it look like a large-size computer? At first you would think that you would want to make the personal computer look like a standard terminal. But the difficulty that this can lead to is that most terminals do not have the ability to receive or send data files to the computer; they are simply for the entry or display of data. They are not intended for storage. So emulating a particular terminal allows a micro no more capability by itself then it would have with any particular terminal.

After conquering the communications software issue, the third major requirement is for application-to-application software. This type of software is only now coming onto the market and represents a huge opportunity for the future. It consists of, for example, the ability to move information from the host data base management system (DBMS) on inventory to an application in the personal computer, such as word processing or spreadsheet. Some short-term solutions are very product- or application-specific. The long-term need is for more general packages that will be available for a wide range of host computers as well as personal computers.

The first software products coming to market in this area are either from those vendors whose software supports large CPU data bases or from other vendors wishing to tap into those host CPU data bases through personal computers. Visicorp, the company responsible for marketing Visicalc as well as other software packages for personal computers, has announced that it will offer personal computer software that will tie in very closely with the Mark IV data base system from Informatics General Corp. and with data base products from Applied Data Research, Inc. Cullinet Software, Inc. has announced that it will offer an IBM Personal Computer capability software package that will allow users to access data easily from their host DBMS. Other such relationships have been formed between University Computing Corp., a manufacuter of IBM mainframe software products, and Context Management Systems; Inc. for their Context MBA package for the IBM Personal Computer; and between McCormack & Dodge Corp. and Lotus Development Corp.

Many large organizations have had to develop their own software for personal computers that allows data displayed in terminal mode to be captured by a personal computer. Some of these programs include editors which allow selective capture of rows or columns of items and converting them to Visicalc-type files inside the personal computer's data base.

Despite this initial progress, to date no products have been introduced that allow easy, generalized access to IBM data bases such as IMS (DL/1) or the new DB2. Such

products are expected to be on the market soon from a variety of vendors — both IBM and independents. It is even thought that some of these will be compatible with IBM's query languages such as Query-By-Example and SQL.

The long-term solution to easy connection of personal computers to mainframes will not be through a wide diversity of software programs. Rather, it will be through the development of standards that will apply to products from a wide variety of hardware and software vendors. IBM has begun to push for acceptance of its new Document Interchange Architecture (DIA) and its Document Content Architecture (DCA) as standards that can be used throughout the computer industry. Regardless of how they are perceived from a technical point of view, it is highly likely that they will become every bit as much a fabric of the industry as has IBM's Systems Network Architecture. DIA and DCA are already being used in the implementation of software for some of IBM's Personal Computer products. These architectures will become standards for people writing software for IBM computers and, eventually, for other computers as well.

DIA is used as the common language and methodology for information exchange in IBM office systems. Displaywriters can easily transfer documents to the IBM 8100 running DOSF and onto the host CPU running the Distributed Office Support System (Disoss). This allows the document then to be displayed on a 3270.

IBM recently announced that Profs will have the capability to exchange text documents with the Displaywriter some time next year. Also, IBM recently released a statement of direction which demonstrated its intent to make office-oriented software for the System/38 compatible with both DIA and DCA. Unfortunately some older office systems such as ATMS may not be made DIA/DCA compatible in the near future, if ever.

Already, independent vendors are establishing their own protocols. Because so much communications on today's personal computers is done using the asynchronous Ascii terminal protocols, this has been used as the basis of the Microcom Network Protocol (MNP) from Microcom, Inc. This protocol is already supported by GTE Telenet Communications Corp., Apple and Visicorp. MNP is a generalized file transfer protocol, providing complete error checking even in asynchronous mode, that can allow transfer of data among diverse personal computers as well as personal computers and mainframes. While it remains to be seen how successful MNP will be, it has already attracted at least one imitator, Data Systems of Baton Rouge's Blocked Asynchronous Transfer protocol, or Blast.

What does a prospective user of a personal computer have to look for in order to hook up successfully to a mainframe? The need for the compatible terminal type as well as compatible software has already been mentioned. Just as important is the cooperation of the people running the mainframe computer operation. Because such computers are often run full-time with existing applications, the information center has been created in many organizations to support end-user computing. While some information center managers have tried to stifle the use of personal computers by supporting only terminals, there is a definite trend toward having full support for personal computers. This usually means that the information center staff is responsible for providing the software for the micros that will allow easy access to the data stored on the mainframes.

Another area that is receiving increasing attention is security. Movies and television have demonstrated that personal computers can be used to gain access to mainframe computers. Most software programs that run on host computers have very rudimentary security checking because designers did not anticipate how easily their systems could be broken into. Since microcomputers make it easier to crack large systems, it is anticipated that enhanced security will be required on virtually all large mainframe systems, and even some personal-computer-based data systems.

When information access is discussed it is usually from the perspective of downloading data from the mainframe to the personal computer. Normally, this will be the usual direction of data flow. However, there are applications that require uploading to the mainframe. The resolution to this problem will be to move the editing function from the mainframe to the personal computer — again, a solution that is now only beginning to be explored.

A related situation involves the proliferation of personal computers beyond the office environment — to the home and locations where portable systems can be used. This presents three additional problems to the typical computer operation. First, there are not enough dial-up facilities provided by most data communications operations. In most IBM shops, the preponderance of terminals are on dedicated lines. Secondly, security on dial-up facilities is inadequate for many sensitive applications. Finally, the diversity of personal computers, particularly portables, will require multiple versions of the cooperative software that runs in these systems. This is a costly situation and will be remedied only when particular personal computers become standard or when standard architecture is widely accepted.□

Direction For The Information Age

Decision support systems (DSS) have been around for a decade, but the proliferation of microcomputers and their interfacing with mainframes have only recently popularized this approach to end-user computing.

Some advocates claim that the concepts of DSS and the software tools falling under that product category are finally delivering the early promises of management information systems by directly addressing management's need to become more effective rather than concentrating on further administrative cost efficiencies.

By Warren G. Briggs

Originally, DSS was a term used to identify software applications that supported less structured management decision-making activities. The term was used to play up the difference between this purpose and the use of computers for automating well-structured clerical and administrative tasks — the traditional data processing functions of payroll, accounting, inventory records and so on.

This growing acceptance of DSS is beginning to modify the early definition of decision support tools as the functionality of the software expands and as vendors discover the marketability of products categorized as decision support systems. Some functions and applications of these products are really not full decision support systems, but simply enable managers to browse easily into corporate as well as external data bases to discover emerging opportunities or problems or to be assured that all is under control.

The widely reported systems used by the chief executives of

Northwest Industries and Merrill Lynch, Pierce, Fenner and Smith are largely utilized for flexible online access to operational data several levels down into the organization — thus eliminating the delays and filters of traditional reporting systems. While these are huge systems, they rarely directly "support decisions," and might better be called "executive information systems." At the other extreme, the microcomputer spreadsheet packages, of which over a million have been sold at under $500 each, are hardly "systems" and are used by lower-level managers. Nonetheless, the simplicity and pervasiveness of these tools, and their recent interfacing with data bases make micro spreadsheets the driving force of DSS applications.

DSS Software Functions

The spectrum of functions generally attributed to DSS-type software tools is summarized on page 29. Some DSS software tools provide many, or even all, of the functions listed, though perhaps at a cost in price, complexity and equipment requirements that exceed the benefits for some applications. Examples of comprehensive products include Express from Management Decision Systems, Inc.; Xsim from Chase Econometrics/Interactive Data Corp. (CE/IDC); Strategem from Integrated Planning, Inc.; and EIS from Boeing Computer Services Co. Other products originally noted for functions outside the DSS spectrum have had features and interfaces added so that they were able to compete in this marketplace. Examples include SAS Institute, Inc.'s statistical analysis system, Cullinet Software, Inc.'s data base management system and several data inquiry languages such as Information Builders, Inc.'s Focus, Mathematica Products Group, Inc.'s Ramis and Dun & Bradstreet Computing Services' Nomad.

The end-user orientation is a feature common to all decision support applications. This implies ease of use, responsiveness and self-documentation, which is not expected of mainline data processing software products. While there are obvious advantages of combining many functions into a single package, the unique power of more specialized packages is a trade-off that must be considered by the end user. For example, many of the newer spreadsheet packages include data manipulation, graphics and even word processing functions, but rarely deliver the performance of packages dedicated to those functions.

As recently as a year ago DSS software tools were segregated by whether they operated in the microcomputer or mainframe environment. However, dramatic and continuing cost-performance improvements and associated marketing thrusts have made the personal computer a distributed processing tool for accessing a variety of mainframe-linked information resources both contained within the corporate information structure and available from public services.

Access to Public Data: The most commonly available micro-mainframe interface involving DSS-type software products is the downloading of data from time-shared vendor sources into micro-based analysis and display packages. For example, CE/IDC offers the Financial Exchange package, which downloads data from its mainframe into a Microsoft Corp. Multiplan or Visicorp Visicalc microcomputer spreadsheet format. While this interface product is a simple and inexpensive supplement to well-known spreadsheet packages, users must have authorized access as subscribers to the CE/IDC financial and economic data.

Data Resources, Inc. (DRI) provides similar interfaces to microcomputer spreadsheets with two products, one directed towards more intensive users and one towards less intensive users. The former might use the DRI Link package and service to download data or the results of a mainframe program analysis into a Supercomp-20 spreadsheet package from Access Technology, Inc. for use on a supermicro. The less intensive user can access the DRI files with Visicorp's Visilink package, downloading so-called Datakits of information into a Visicalc format. Boeing Computer Services also provides a micro interface to their time-shared EIS modeling system and data banks.

Each of these products demonstrates the systematic and efficient distribution of the DSS functions between the micro and the mainframe. The micro serves as a terminal, while efficiently recalculating and displaying the consequences of repetitive "What if?" queries and other unstructured analyses typical of DSS user applications. Furthermore, the micro does these tasks at no incremental charge, with user-friendly software and the self-control, security and responsiveness features of a detached micro. Meanwhile, the mainframe does its part of the distributed functions through efficient large-scale, professionally updated data storage and powerful time-sharing packages for occasional use in financial modeling or statistical analysis calculations that are beyond the micro's capability.

Access to Private Data: Data downloading from an organization's transaction processing and accounting records often meets with important administrative as well as technical complications. For example, at a major bank noted for its progressive management and computer sophistication, the accounting department firmly denies access to all transaction and customer files, arguing that its responsibility for secure bookkeeping and customer privacy precludes any direct access for DSS-type applications, however useful or high-level such applications might be. Such an attitude is no doubt reaffirmed by recent press reports on the exploits by online hackers.

A product in development by Cullinet Software addresses the ad-

ministrative as well as technical interface to corporate records. Its Information Database package will extract and aggregate preauthorized items from a mainframe data base and provide for a buffered downloading to micro spreadsheet and analysis packages. The corporate data administrator can thereby establish and monitor which DSS end users can access which items.

Several leading vendors of mainframe-based DSS software have recently introduced microcomputer subsets of their products to address this demand for distributed functionality. Notable examples include Micro FCS and FCS-EPS from EPS, Inc.; and Interactive Financial Planning System (IFPS) and Micro/IFPS from Execucom Systems Corp.; Micro-Model and Model from Lloyd Bush Associates; Micro W and System W from Comshare, Inc.; and Microforesight and Foresight from Information Systems of America, Inc. Still other leading software vendors have developed versions of their mainframe product for the more powerful supermicrocomputers. Examples of this approach include Express from Management Decision Systems, Inc.; Strategem from Integrated Planning; and Cuffs from Cuffs Planning & Models, Ltd. These supermicro versions provide a less expensive way to introduce applications and service less complex requirements, while enabling growth as necessary to the full package through time-sharing or a corporate network to a mainframe.

Another trend, less obvious in the software products themselves, than in how they are acquired and administered, is the integration of various computer-based activities into the institutional information resource. Data processing, office automation, telecommunications and DSS are being consolidated and coordinated at senior executive levels in many progressive organizations. This structural shift reflects the technical maturity of these activities, as well as their increasing importance to the organization. The challenge is to achieve the efficiencies of this consolidation without destroying the initiative which has enabled innovative applications using DSS tools.

A critical initial step in the evaluation and selection of any software product is a realistic and thorough assessment of current and potential end user needs. The nature of DSS applications complicates this process since these needs are much more difficult to define and anticipate than are typical data processing applications. Also, the skills, attitudes and expectations of the end users are critical to the software product evaluation. For example, a payroll, order entry or inventory control software project may indeed be large and complex, yet the inputs, processing and outputs are quite definable within reasonable ranges of predictability.

On the other hand, with DSS applications it is difficult to estimate how much ad hoc data inquiry, spreadsheet analysis, and reiterative graphics display end users will consume. Effective DSS applications inspire more questions — again in contrast to data processing applications where some end point is evident. DSS is obviously a supply-driven demand. If the results seem useful, resources are quickly exhausted, but (and just as important) a disappointing and oversold DSS application will be rejected and underutilized.

The coordination of end-user needs assessment is difficult in large organizations because of the obvious propensity for isolated requirements to be promptly satisfied with stand-alone microcomputer or time-sharing systems. Such initiative, often in spite of existing centralized controls on computer acquisition, has been important in demonstrating the value of DSS in its early stage. However, as decision support systems become involved in the corporate information structure and the potential costs and benefits escalate, a coordinated assessment process becomes essential. Much more is at stake in large organizations than simply a wrong choice among several microcomputer spreadsheet packages. At issue is the opportunity to enhance or to frustrate the productivity of key personnel whose daily cost exceeds the price of most micro packages.

Even worse than discovering a wrong choice among DSS software tools is the situation which sometimes arises when a successfully used system must eventually be replaced because it will be inadequate for future requirements. Again the contrast to data processing software changes is evident. If a payroll program, for example, needs to be replaced, only a few data processing and administrative professionals are involved, but with the replacement of a DSS tool the productivity of key managers is impacted.

One area which also requires critical thought when choosing a DSS is which executives to support. Before too much end-user demand is generated in this process, it is important to establish some criteria and priorities to help allocate the DSS resources. The critical success factor concept developed by Rockart and others at MIT has been useful in guiding large data processing project developments towards the highest payoffs. DSS applications have by now matured in some firms to the scale where it is worthwhile to concentrate on introducing these systems to the managers and professionals whose performance and productivity improvement are among the most critical to the organization.

This end-user needs assessment effort should result in at least a preliminary specification of what is needed and desired of a DSS software package for both immediate and eventual requirements. Answers to such questions as these should be sought:

- Which functions are essential or desirable?
- To what extent will DP experts support end users, as opposed to having end users developing their own skills with the

new package?

- What hardware resources are available? Is time-sharing a viable alternative? Are microcomputers and local-area networks emphasized?
- What special security and privacy issues may constrain data access and control?
- What data can and will be made available? Will there be administrative constraints? What will be the cost and value of vendor-supplied data, and will there be separately maintained records?
- What graphics are needed? What will be its function, for interactive analysis or presentation-quality reporting?
- What word processing and final-report formatting is needed?
- What types of financial modeling are desired? Spreadsheets or equations and financial or statistical functions? What about data access and manipulation; will downloading and consolidation capability be needed?
- Is compatibility needed with other vendors' software and hardware, such as external data bases, local data base management systems, micro networks, graphics, printers and plotters?

The next steps towards selecting an appropriate DSS software package include the development of prototype applications and comparative benchmark tests of computer resource requirements. No amount of vendor demonstrations can capture the realism of representative end users working with prototype implementation in their own environment. This exercise can shake out potential difficulties with end-user training, documentation, interfaces, and computer needs. It can also confirm or modify the end-user needs assessment, since with DSS-type "you really don't know what you want till you try it." Obviously vendors, consultants and in-house experts must participate in the prototype project, yet they must not obscure the end-user reactions. Eventually the experts must withdraw, and the product's ability to serve its users should be discovered early.

The development and running of typical benchmark applications are helpful for comparing some aspects of alternative DSS-type products, yet these tests are less useful criteria for end-user evaluation than they are for data processing software evaluation. In the payroll processing application mentioned earlier, the design of a benchmark test is quite straightforward and comparative results among competing packages can explain much of the relevant differences. By contrast, typical benchmark specifications are hard to prepare when end user needs are still evolving. Also, relative computer costs are a small part of the total comparison among alternative DSS packages. More relevant are harder to measure attributes such as user friendliness, flexibility, responsiveness, visual appeal and so forth.

A final step in this process is to look beyond the product itself to the health and attitude of the vendor. Obviously some excellent and innovative products come from new or obscure firms. But this is a risky as well as exciting industry, with hazards ahead even for those firms which are currently prosperous. A prosperous vendor is obviously more likely to continue providing modest cost updates and extensions to their product. Other advantages in choosing the best-sellers are that people skilled in using the product are more readily available, as are such supporting products as training seminars, textbooks and research publications. As with any rapidly growing industry, shakeouts and consolidations are beginning, and some innovative small software firms are joining established leaders. For example, Peachtree Software, Inc. is now part of Management Science America, Inc. and Mathematica Products Group, Inc. has been acquired by Martin Marietta Data Systems. Other entrepreneural products are being approved and marketed by large-systems firms, such as IBM and Digital Equipment Corp.'s microcomputer divisions.□

SPREADING THE WEALTH OF DBMS

By Shaku Atre

Vendors of data base management systems (DBMS) are sounding more like car dealers every year. They claim to have the best product that will fit any environment and do any type of processing. How does the DP executive wade through this morass of claims? Knowing the developing trends will help managers responsible for selecting DBMS products evaluate these systems. This article explains the major trends in DBMS — emerging data models, distributed data bases, data dictionaries, programming languages and applications developers, prepackaged applications software integrated with DBMS, report writers and ad hoc query facilities and product integration and so forth.

There are four major types of DBMS: hierarchical, network (Codasyl or non-Codasyl), inverted file and relational. These categories are not arbitrary, nor do they arise from vendor terminology. They describe the types of data models that a DBMS supports. A data model is a description of structural properties that define all entities represented in a data base and the relationships that exist among them.

The DBMS on the market today are neither purely hierarchical nor purely network, inverted file or relational; they are some combinations of these four types. Most of the DBMS that a buyer encounters have evolved over the years, and they have borrowed the features from each other's offerings. A DBMS is labeled as hierarchical or network when a large percentage of its architecture is based on a hierarchical or network data model. Although hierarchy is a subset of Codasyl-network architecture, the hierarchical DBMS are considered separately because of the eminent presence of IBM's IMS.

The inverted file is more of an implementation issue than an architecture. But there are some quite successful DBMS products that use this implementation feature as the basic architecture. As a result, they are also considered a separate category of software. Software AG's Adabas is an example of an inverted-file DBMS.

And then there is the relational category. It took about a decade after the advent of the relational model before relational systems became fashionable. Ironically, most DBMS have turned into relational products almost overnight.

It is important for buyers to familiarize themselves with features of relational systems so they can make educated evaluations of products. Many vendors claim they have relational DBMS products if they provide a table view of data. Many companies have incorporated relational-like features in their DBMS, with some vendors featuring more relational capabilities than others, but very few systems available today have pure relational designs.

Adabas, Cullinet Software, Inc.'s IDMS/R, Applied Data Research, Inc.'s (ADR) Datacom/DB and Computer Corp. of America's Mod-

el 204 all have relational features, but they are not wholly relational systems.

In a relational DBMS, the pointers are not stored with the data. The relational operators (for example, join, project and intersect) should be supported. In addition, relational systems must provide flexibility; the user should be able to add more attributes to a relation without affecting the other relations or existing applications.

There are two major classes of DBMS products available. One class consists of the products that hardware vendors market and support. The DBMS can be implemented only on the vendor's or on plug-compatible hardware. Users should avoid buying DBMS software simply because the hardware vendor offers the system. While many products from hardware vendors are good, these vendors may or may not have an interest in developing efficient software.

The other class consists of the products that independent software vendors market and support.

Vendors are moving towards providing a relational-type DBMS product. The announcement of IBM's DB2 has given relational systems a strong boost, just as the introduction of the IBM Personal Computer legitimized the micro. Other vendors will be spending more on research and development of their relational prototypes.

The performance of the relational DBMS leaves a lot to be desired when running on today's hardware. As a result, the vendors will have to provide a DBMS that will make use of all four data models and will support all views.

These views can be described as a layer cake. The bottom layer would consist of a network (Codasyl or non-Codasyl) with embedded pointers or of an inverted file without embedded pointers or a combination of both used for implementation. The second layer would provide a hierarchical view for applications programmers in the development center. The third layer would represent a relational or table view with a procedural language, and the top layer would be a fourth-generation, nonprocedural query language for end users of the information center.

IBM's IMS will continue to be a three-layered cake; that is, IMS will be implemented using a hierarchical view, but not with the network structure, although network structure enables the user to implement complete mappings more easily. The relational view will be supported by IBM's SQL. Query-by-Example (QBE) could be used for supporting the relational view, but it can also be implemented without IMS — the major drawback of QBE is its high resource usage. DB2 could also represent the top two layers.

The major benefit of implementing and using a DBMS is the interrelatability of data from different parts of an organization. But in some companies, the management and staff are not ready for "sharing." The DBMS of tomorrow is expanding its influence more and more on the user community. The successful DBMS will support the architecture depicted in the accompanying diagram on page 33.

The industry is moving toward a distributed data base environment. The major characteristic of a distributed data base environment is that it presents a "single-system image" to users. The central version of the data base will be stored on the mainframe, and individual parts, or "specific views" of the data base, will be downloaded onto microcomputers.

The "specific-view generator" would be transparent to users and could be a query type of interface. Users will be able to update the specific views using microcomputers, and these updates or changes will be batched and transferred to the central data base once, two times or a few times a day, depending on the urgency of updating data. The downloading capability will be supported by the DBMS.

What should the user do in order to be ready for this distributed environment? Distributed processing involves the distribution of data, functions, resources and responsibilities.

One solution is to design the data base so that it will be made up of many homogeneous modules that could be taken off and put together in assembly fashion. The specific-views concept would be difficult if this model was not used.

The DBMS could be implemented with specific views in an information center type of environment and with central views in a development center.

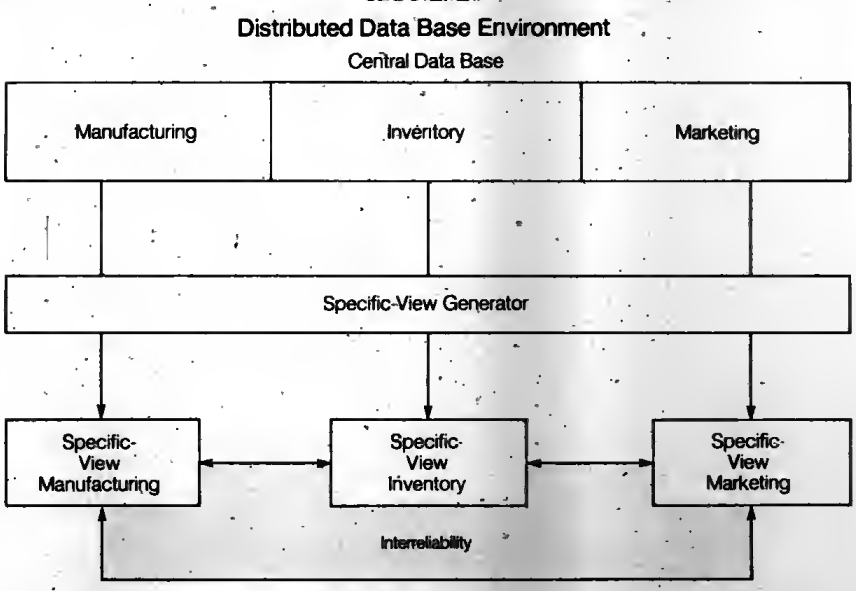
What are the implications of this trend? As relational systems and fourth-generation languages make the DBMS easier to access by users unfamiliar with data processing, microcomputers will play a greater part in the use of DBMS. Some recent software announcements are betting on that trend. Examples of these are IBM's DB2 with QMF and DXT, Cullinet's introduction of IDMS/R, Software AG's announcement of Natural 1.3 with relational operators and ADR's Ideal with relational operators.

Almost every DBMS vendor is jumping on the relational data model bandwagon, with vendors of Codasyl DBMS playing down their association with Codasyl.

The buyer should evaluate how much emphasis the vendor is expending on the marriage of micros and mainframes. The major winners on the micro side could be the IBM Personal Computer and its compatibles, Apple Computer, Inc.'s Lisa and Digital Equipment Corp.'s Professional Computer.

The buyer should try to determine:

- Does the vendor provide relational-like capability? If so, how will that be implemented?
- Is there any interface between the mainframe and micro? How is that implemented? What are the uploading and downloading capabilities?
- How can security be implemented; through physical, logical or encryption methods?
- Are there any prototypes or beta test sites already running?



Another major component of any DBMS product is the data dictionary. In a data base environment, one of the major objectives is the sharing of common data by multiple users. To realize the objectives of correct data, minimum redundancy and control of data usage, a centralized control mechanism is mandatory. The data dictionary is the primary means of satisfying these objectives. But the decision to acquire and to implement a data dictionary should not be taken lightly. The effective use of the data dictionary will probably require some organizational and procedural changes such as the addition of a person responsible for data dictionary or data base administration. Acquiring a data dictionary is a commitment, just as acquiring a DBMS is a commitment.

The software product is called a data dictionary. The data base created using the product also is called a data dictionary. The data dictionary stores such information about data as its origin, description, relationship to other data, usage, responsibility and format. It stores data about data. The data dictionary is a guide and contains "road maps" to the data base instead of raw data.

There are two types of data dictionary products: free-standing and integrated. A free-standing data dictionary package is a separate product in addition to the DBMS package, whereas an integrated data dictionary is a part of the DBMS product.

In the case of an integrated data dictionary, the data descriptions exist only once in the system, and the descriptions are stored in the data dictionary. In a free-standing data dictionary, an option exists whether the appropriate data descriptions will be retrieved from the data dictionary or supplied otherwise.

The characteristics of an ideal data dictionary system include:

- The data dictionary should be integrated with the DBMS. The evaluator should be very much concerned about the in-house developed bridges between the DBMS and nonintegrated data dictionary package.
- The data dictionary should support various versions of the documentation (for example, the test versions and the production version).
- The data dictionary should support the data base design process acatively.
- The data dictionary should support editing as well as integrity checking during production runs.
- The data dictionary should support on-line as well as batch processing.
- The data dictionary should have the capability of storing system as well as user-maintained information.
- The data dictionary should be

easy to use. It should have a feature for storing on-line transactions. The users should be able to initiate these transactions without having to remember procedural details.

- The data dictionary should be able to direct the data base processing activities to the proper destinations in distributed data base environments.
- Security and auditing features should be implementable with the help of the data dictionary.

There is a recent trend among suppliers of DBMS vendors toward having the dictionary as an integrator for all of the related software packages, including a query language processor, a teleprocessing monitor and applications development software, as well as support of the information center type of environment. Some examples are Cullinet's Integrated Data Dictionary (IDD), Software AG's Predict, ADR's Data Dictionary and Cincom Systems, Inc.'s Total Data Dictionary. However, some nonintegrated data dictionaries on the market do a good job. Examples of these are Data Manager from MSP, Inc., Data Catalogue from Synergistics Corp. and UCC Ten from University Computing Co.

IBM has not entered the arena of the integrated data dictionary wholeheartedly. It does not look as though IBM intends to integrate its IMS DB/DC dictionary with IMS in the true sense of integration. It remains to be seen whether in the next few years IBM will supply a data dictionary as microcode on 4300 and 30 series mainframes, as it has done with the System/38.

Although the industry has created a lot of hoopla about fourth-generation languages recently, it will be at least five years before there is a major investment in programs using these languages. That means programmers are most probably versed in the third generation rather than in the fourth; so in order to be able to create applications programs in the development center, the DBMS with a fourth generation language would have to have an interface with Cobol.

The consumer should also investigate whether the vendor provides an applications development feature with the DBMS — not just for the batch world, but to be used in interactive mode for boosting the applications programmer's productivity. IBM is putting major emphasis on application development facility (ADF) for IMS, Cullinet is emphasizing ADS/On-line, Software AG is promoting Natural, ADR is marketing Ideal and Cincom is selling Mantis.

The major trend of the mid to late '80s will be prepackaged applications software that will have data integrated in the data bases, and this data will be able to be accessed via the DBMS. Of the DBMS vendors, Cullinet has already made a strong move into integrating a number of available applications systems with its IDMS data base system. A number of other DBMS vendors are working with the vendors of prepackaged software (for example, Software AG) to introduce DBMS-compatible versions of these products.

Any DBMS package that does not support a report writer or ad hoc query facility is doomed for failure. These facilities represent the decision support system or information center type of environment. The DBMS should directly interface with a report writer facility that allows users to select, retrieve and print data easily in an on-line mode. Output should optionally be directed either to a printer or to a terminal.

The ad hoc query capability should be available outside of the DP department for nonprogrammers, assuming proper security measures have been implemented. IBM's IMS contains a major hole in its product line when it comes to these facilities. QBE and SQL/DS tried to fill the void, but both require heavy resources. DB2 should run on MVS/XA as well as on VM/XA with QMF and DXT, but these products are said to be major resource hogs.

Intellect, marketed by Artificial Intelligence Corp. and by Cullinet as On-Line-English; Focus from Information Builders, Inc.; Ramis from Mathematica Products Group, Inc.; Software AG's Natural; and ADR's Ideal have varying degrees of user friendliness. Focus and Ramis seem to be quite successful.

The DBMS vendors will be emphasizing ad hoc query capability as well as the capability of developing prototypes before building the full-fledged system. With prototypes, users can see what system they are going to get and could recommend any changes early in the development phase.

The successful DBMS vendors will be integrating the following components (each piece charged for separately though) in the next two years.

- Data base manager.
- Teleprocessing monitor.
- Data dictionary.
- Report writer and fourth generation query language.
- Applications development package.
- Auditing tools.
- Prepackaged software.
- Downloading and uploading capabilities between mainframe and micros.
- Graphics and statistical representation performed with micros.

As months pass, more and more publicly available data bases will be accessed and more and more novices will be using data bases on microcomputers. Without hesitation, it can be said that society will be more and more dependent on the data base technology.o

Shaking Up The Uses Of Information

Today there are more than 100 products that claim to be data base management systems for microcomputers. Choosing the right system depends on the computer literacy of the end user. And price is not necessarily a good guide in the selection process.

By Gordon C. Everest

For most users of microcomputers, the data base management system (DBMS) is the most important piece of software acquired. The bad news is that it is very difficult to match various features from a bewildering array of choices to the particular needs of the buyer.

Whenever users need to keep files of data on a computer, they are foolish not to use a DBMS. A well-chosen DBMS can greatly reduce the cost of bringing data under control, of keeping it up to date and of developing data intensive applications systems. It can greatly increase the availability of information to those who need it, when they need it.

A DBMS provides a middle-of-the-road solution between acquiring an off-the-shelf applications package, which is often a heavily compromised solution to the user's needs, and building the system from scratch using some conventional programming language such as Basic or Pascal. For most users, writing their own programs is no longer a desirable alternative; it is too costly to build systems, takes too long to build them, and they are too inflexible once built.

The graduate school of management at the University of Minnesota has been surveying commercially available microcomputer DBMS for several years. The fourth edition of the survey will include more than 60

systems, all running on microcomputers. To be included in the survey, a system must cost under $25,000 for both hardware and software.

In the fall of 1980, 40 systems were identified, 70 in the spring of 1982, and today there are about 150 commercially available DBMS for micros. About 10 of these are no longer sold. With increasing rapidity, new and better systems are being brought to the marketplace, but new does not always mean better. The quality of available DBMS functions varies greatly.

There should really be nothing different about DBMS on microcomputers and DBMS on large mainframes. The needs of the users are the same, and all the required functions are the same. The main memory size of some microcomputers today equals the size of a memory partition available to the DBMS on most mainframes. What is different is the size of the files that can be created and the speed with which they can be processed.

Some mainframe or minicomputer DBMS vendors have already implemented their systems in microcomputers — IBM's Brads; Gemini Information Systems, Inc.'s DDQuery; Information Builders, Inc.'s Focus; Relational Technology, Inc.'s Ingres; Micro Data Base System, Inc.'s MDBS; Boeing Computer Services Co.'s Micro BCS-RIM; Oracle Corp.'s Oracle; and International Data Base Systems, Inc.'s Seed. All generally claim their systems to be functionally equivalent in the microcomputer versions.

Several vendors are currently hard at work developing interfaces between DBMS files on a host mainframe computer and a network of micros.

Making host computer data available to micros also has its drawbacks. Greater capability is needed to control access to private and confidential data. Furthermore, if local users are allowed to collect and enter data locally and update the central files, greater control and validation must be exercised to ensure data quality.

What is exciting about DBMS on microcomputers is the generally wider range of functions provided than is found on most mainframe products. Some systems available today include features such as high-level ad hoc query languages, powerful report generators, statistical and graphical output, data entry/display-screen management and menu handlers, even integrated with word processing and spreadsheet programs. The user is more in control of the data (and responsible for keeping it accurate and up to date).

Perhaps the greatest difference between mainframe and microcomputer DBMS stems from the assumed operating environment. The user of a microcomputer is inherently on-line. Most microcomputer software developers have paid much more attention to the screen interface, keeping the user appraised of what is happening, providing menus and Help screens and letting the user be more in control of the processing steps. It is expensive to redesign DBMS existing on large computers. Vendors are having a difficult time breaking out of the "batch processing syndrome." On-line products for use on the mainframe have only recently emerged — Cincom Systems' Inc.'s Mantis; IBM's DMS; Culhnet Software, Inc.'s Adds-Online; Software AG's Natural; and Sperry Corp.'s Mapper. The facilities of such systems are normal parts of many micro-based DBMS. In fact, a micro DBMS developer is sometimes better off never having known the big systems DBMS world. It is different to write a program knowing that the user is there every moment during execution.

When seeking a DBMS, the first step is to decide what type of user you are. At one extreme is the novice end user who needs a menu-driven system with screens for data entry, ad hoc query (by forms) and Helps, plus a comprehensive report generator. At the other extreme is the systems developer who needs a tool for building a turnkey system for a specific applications environment.

In between these two extremes is a command-driven system that always waits for the user to specify what he wants the system to do next. This implies that the user must first study the available commands before using the system. Generally, such a system will permit users to build up and to store sequences of command that can later be invoked from the command level or from within other command files. This allows the user to begin developing applications systems. In fact, with microcomputers, the distinction is increasingly fuzzy. The person at the terminal is at once the end user, the developer, the operator and the installation manager.

Many users who start out as novices soon become more sophisticated. They want to be able to prestore queries, report definitions and command sequences that they use over and over — perhaps they even want to set up something on the system for another novice user.

On the other hand, rarely should any consideration be given to writing any procedures in a conventional programming language such as Basic, Pascal or Cobol. Such languages, even augmented with a data manipulation language like that proposed by Codasyl, are low level languages with respect to data processing. They require the user to navigate through a data structure, retrieving and processing one record at a time. Using languages at this level to build applications systems should be the last resort. On a microcomputer, it is not even acceptable to have exits to user-written code — such a facility is often an escape for the DBMS developer who did not do what he should have done in the first place.

Beyond the menu-driven interface, where the system controls the dialog, a good microcomputer DBMS will provide a high-level command language. A high-level

data language provides single commands that operate on the whole file at once, with the possibility of even operating on multiple files. Components of such a language select records from a file that satisfies a Boolean expression, projects named fields from those records, derives additional values for each of those retrieved records, presents the information from the records sorted, and with appropriate titles and headings, and calculates statistics (count, sum and so on) on certain fields for the whole file or at "control breaks." Commands should be available to invoke a user-defined or system default data entry/display screen or to generate a previously defined report.

Commands should be able to be given to the system for immediate execution or stored in a file for deferred execution. Such a command file can be treated like another command in the system. Also, a menu should be treated like another command, capable of being invoked as an immediate command or from within a command file. Likewise, taking a choice in a menu invokes another command or set of commands.

The above discussion is intended to provide a brief idea of what to look for in selecting a micro DBMS. A comprehensive DBMS providing menus for a novice user, a high-level command language for the more sophisticated user and facilities for the applications system developer is considerably more complex than a word processing system or a spreadsheet program. It is more difficult to design and build, and it is even more difficult to comprehend and use. Most word processors and spreadsheet programs are good to excellent. On the other hand, there are some pretty poor systems sold that purport to be DBMS.

The underlying simplicity of spreadsheet programs, like Visicorp's Visicalc and its clones — Microsoft Corp.'s Multiplan, Lotus Development Corp.'s Lotus 1-2-3 and Context Management Systems' Context MBA — may account for their predominance. This is also the case for word processing. It is easier to comprehend the underlying structure of the data or text and to conceptualize the operations on that structure.

One clear trend that is emerging is the increased integration of applications packages with DBMS. Lotus 1-2-3; Apple Computer, Inc.'s Lisa; and Epson America, Inc.'s QX-10 have integrated various parts of data base management, word processing, stalistics, graphics, spreadsheets, financial modeling, time and project management and accounting. Visicorp's Vision and Micropro International Corp.'s Starburst provide mechanisms for integrating various software packages.

Is DBMS viable on microcomputers? Absolutely. This is evidenced by the large number of systems being offered for sale and actually being sold. Some vendors are reporting cumulative sales approaching 100,000 copies. Some systems on micros actually migrated from larger machines. The University of Minnesota has identified over 140 commercially available DBMS on microcomputers from Apple and Atari Corp. to supermicros based on Motorola, Inc.'s 68000 CPU. They range in price from being bundled in the price of the hardware to more than the cost of most micros.

Several factors could lead the buyer astray in choosing a system. First, price is no indication of a product's value. With the cost of selling one more copy being so low compared with the cost of development, the pricing of software is absolutely arbitrary.

Do not be misled by the reported number that has been sold. That is more a function of marketing than of technical excellence, ease of use or continued support. And the level of the marketing effort is often a function of which vendor was able to attract the most venture capital.

Beware of the premature announcement or the plans for a next version that will provide more functionality. Select a DBMS for what it is today. See it working on someone else's computer or as a demo, read the manual and try it out.

In order to pick the software and hardware properly, do some initial sizing of your needs. This means estimating file sizes to be stored on secondary storage or disk devices. Here are some guidelines:

- Floppy drives from 130K bytes to 170K bytes, such as on the Apple IIe, Atari or Commodore Business Systems, Inc. Commodore 64, will manage files with a few hundred average-size records, which is barely feasible for any serious records management.
- Lower capacity business micros with 350K-byte floppy drives, such as the IBM Personal Computer, Digital Equipment Corp. Rainbow, Osborne Computer Corp.'s Osborne I, and Texas Instruments, Inc.'s Professional Computer, as well as micros from Wang Laboratories, Inc., Televideo Systems, Inc., or Zenith Data Systems Corp., will manage files with several hundred to a few thousand records.
- Higher performance micros, such as Vector Graphic, Inc.'s Vector Graphic and Victor Technologies, Inc.'s Victor 9000, will handle files with several thousand records. Beyond this it is advisable to go to a hard disk system — for better speed on disk I/O as well as larger data capacity. Several of the better DBMS require hard disks for any practical and effective application, even though they may technically operate with dual floppies.

Most systems do a credible job of processing one flat file at a time in a single-user environment. However, look at your applications carefully. You may need to be able to process multiple files together. Such processing should not be available only in the command language (as it is only in Ashton-Tate's Dbase II and System Plus, Inc.'s FMS-80), but also in ad hoc query languages (for example, IBM's SQL and Oracle), report

writing and screens for data display and data entry.

The next significant jump in capability occurs when the system will let multiple users at different sites interrogate and update common data files. Such a capability is filled with pitfalls, and few do it well. Some vendors advertise that they do not need a central "file server." Unfortunately, without some locus of global intelligence within the system that services all requests to access data and manage locks, it is practically impossible to avoid a deadlock. Such systems simply pass the buck to the users. Two or more users in different rooms may be requesting data each other has and wait a long time before realizing that one of them must give up (be preempted) the data he is currently holding with lock on. Acquiring a local network with low-level record locking facilities is useless if the DBMS does not make use of that feature — something the multiuser label claims to do.

It is wise to look beyond the household names in DBMS. It is also wise to look beyond those that are heavily advertised or have purportedly sold thousands of copies. Look carefully at the features offered.

Some hardware vendors have (presumably) studied the available DBMS and recommend one or two for use on their systems. They may actually distribute the DBMS under an OEM arrangement with the vendor or may even provide it bundled in the price of the hardware. At least this means the software should work and perhaps be installed for the keyboard/screen codes on the hardware. It will probably be a good choice, but it may not be the best available system since such vendor arrangements are influenced by factors other than technical excellence. Of course, you must still be sure that it matches your needs.

A software publication recently surveyed readers and asked them to name specific software products they were using or planning to use. For micro DBMS, 40% (of the 110 respondents) said they were currently using Dbase II, with the next highest product in use garnering 7.3% of the respondents. In the coming year, 32.4% (of 108 respondents) were considering Dbase II, the next highest mentioned product getting 9.3%. When it comes to DBMS on micros, more people have bought or are considering Dbase II than any other product.

Although Dbase II may be popular, it will not necessarily meet the needs of corporate end users who have minimal knowledge of computer systems. This means that buyers should evaluate systems with their own environments in mind rather than be swayed by the popularity of a particular system.

So what are the strengths and weaknesses of Dbase II? It is a reasonably clean product, both in its design and its bug-free operation. Its usage mode is command driven only. It is possible to issue commands for immediate, ad hoc execution or to build them into a named command file and stored for later execution.

The serious Dbase II user should have a programmer's way of thinking about his task, since there are no menus to lead the user through the system. In fact, it is most distressing to the novice when upon loading the system, it presents him with a dot in Column 1, which means the system is asking "What do you want me to do for you today?"

The system lacks menus, a menu builder, Help screens, default data entry screens, access controls for security, a DATE type, a data item validation, subcounts or other statistics (except subtotals), sorting on more than one field at a time, error trapping from within a Dbase II program, a multiuser capability and derived items in the data definition. Of course, it is always possible for the user to write the low-level instructions to read the records one at a time from two files simultaneously and accomplish the desired processing. However, the purpose of a DBMS is to provide high-level facilities to enable faster system development and ad hoc data retrieval.

Once the DBMS is acquired, the real work has only just begun. You must study your information needs and design data files and major processes to meet those needs. The files must be formally defined in the DBMS. This may require adjusting your file design to fit best the architecture and limitations of the chosen DBMS. Next, you must collect the data and enter it into the computer system in machine-readable form (or transmit it from some other computer). Once the data is in the machine, you need to define output reports and user procedures in order for any special processing to be performed on the data files. All of this implies that people must take time to learn to use the system.

These activities all represent a very large investment of time and money — many times larger than the initial purchase price of the DBMS. The initial cost of the DBMS should be of no concern in deciding what to buy. The choice must be made wisely, assessing the subsequent impact on the user. The consequence of a poor selection costs much more than the few hundred dollars spent for a system. Anyone planning to make extensive use of a DBMS, in developing applications systems or training many users, is advised to seek outside expert help in making the selection decision. In this situation, the computer or retail store salesman is rarely able to give adequate advice.□

1500 organizations can. And do.

They put absolute trust in us.

We're The Cambridge Systems Group. And to date, we've sold 1,500 systems to leading organizations. Our A**2 family of products, ASM2 (Automated Space Management System), ACF2 (Access Control Facility), and ADC2 (Automated Data Center System) offer sophisticated, technological breakthroughs in today's computing environs.

Simply stated, Cambridge software delivers.

Easy-to-use, our software systems present solutions to the important data-processing problems of controlling DASD growth, protecting data against unauthorized disclosure, modification and destruction, as well as managing job scheduling.

For further information on how The Cambridge Systems Group delivers cost-effective value, high performance, reliability and satisfaction to 1,500 organizations, please telephone or write Mr. Shawn McLaren, Director.

He'll be glad to tell you what 1,500 organizations already know: you can trust us.

The Route To Information Access

The information center is becoming the gathering place for managers and professionals who want to use corporate data effectively. Although IBM laid the path for the creation of information centers, companies are finding new routes for delivering this service. This story is an overview of the current developments in information centers. The following story is a corporate view of the operation of one information center.

By Diane M. Flis

The Information Center, first introduced by IBM Canada in the mid-'70s, is evolving in new directions. While many DP sites instituted the information center concept using the IBM approach, many firms are enhancing the IBM model. The main functions of the information center are to facilitate end-user computer access, reduce programming backlog, educate management on the use of computers and to act as a liaison between the growing debate surrounding microcomputers vs. the mainframe. Today, one can find as many forms of the information center as there are corporations with them.

Simply stated, the information center was developed to supply computing power to end users on their terms. The purpose is to enable these users to access directly data and reports with a minimum of prior instruction. The IBM approach was to provide users with the software tools necessary to generate their own reports, manipulate and analyze data as well as modify existing reports. It appears that whatever form or structure the information center takes within a firm, its main objective is finding the best tools to solve a firm's business problems. The ability to provide quick responses to special information requests from users in a cost-effective manner, along with reducing the maintenance programming by DP, is a very desirable benefit. Just how successfully this has been accomplished depends on the organization and its methods of implementation.

ILLUSTRATION BY JON McINTOSH

Vincent T. Pica, first vice-president management information systems operations of E.F. Hutton & Co. in New York, felt that the traditional IBM concept of the information Center "was not robust enough" for E.F Hutton's needs "Our users need a system that does more than retrieve files." E.F. Hutton is moving toward building a state-of-the-art system that it calls its Information Processing Laboratory (IPL). The IPL marries word processing, data processing, graphics and image processing applications. The IPL is built on top of the information center concept in the hopes of encouraging the orderly and efficient use of computer resources. "I wouldn't be surprised if we save $1 million this year," Pica predicted. "By osmosis alone, we will do things in a more efficient manner." Currently, Wang Laboratories, Inc. and IBM personal computers under Microsoft, Inc.'s MS-DOS are being used, with the intent of connecting to a larger system in the future.

Some centers are run under the close auspices of the DP department and others are handled as totally separate entities. Either type, or any variation of it, can be successful if users' needs are met while obtaining assistance from the central DP department.

The DP subsidiary of Fleet Financial Group in Providence, R.I., was given a mandate from its chairman of the board in 1981 to start an information center. He wanted the DP department to provide management with the necessary tools with which they could do business more aggressively and efficiently. "We went directly to IBM and received the textbook mode of the IBM Information Center," Thomas A. Benoit, manager of Fleet's information center, explained. Fleet follows the IBM guideline of not doing custom programming for users and tries not to compete with the central systems control group. "We maintain close control with our users and try to keep them out of any gray areas" Benoit explained. Fleet has started to move away from the IBM model by purchasing software vendors other than IBM. The center now mainly uses Focus, from Information Builders, inc., and Intellect, from Artificial Intelligence Corp.

Conversely, Central Fidelity Services, inc. in Lynchburg, Va., experienced a heavy backlog of applications development activity and found its users contioually in need of simple one-time reports. "We figured that we had to have an information center for our bankers who wanted to design a report either for interim use or as a prototype for long-range use. And the solution nearest at hand was IBM," explained Bill Thomas, manager of the information center. Central Fidelity is still working with the IBM pilot while also working closely with its personnel department and other specialized areas in developing the center.

Sometimes the driving force for implementing an information center may come from users themselves, especially in situations in which these users feel DP is not receptive to their needs. Very often, due to a poor understanding of the program requirements, the user ends up with a system that does not deliver the information he wants. In this situation, the user may instead decide to go outside to purchase his own micro. When this happens, a corporation finds it needs someone to answer user pleas of help. This puts a new burden on technical personnel who do not really have the expertise to answer such questions. "We experienced a proliferation of micros into our staff headquarters, and we needed to maintain control," one information center manager said, noting this phenomenon was a major reason for establishing an information center.

The major point consistently mentioned by managers of information centers has been that in order to run a useful and helpful center, there must be a good working relationship between DP and end users in corporate departments. Consequently, many firms first established a mission and scope with the intentions of starting out small and then growing, with great concern given to the learning curve for those who staff and use the center. "At Fleet, we try to touch base at least once every quarter with all of our users just to monitor their progress" Benoit stated.

Some centers are run under the close auspices of the DP department and others are handled as totally separate entities. Either type, or any variation of it, can be successful if users' needs are met while obtaining assistance from the central DP department. Though many DP professionals fear losing control of the corporation's DP functions, and often the information center is indicative of this, in some cases the center has reduced burdens on the systems programmer and alleviated stress between DP and end users. E.F. Hutton's Pica explained that "no data processing professional will ignore a user's needs. The solution must be a better system. And the guy who doesn't solve the user's problem will ultimately just create a larger one."

No matter how adept end users may become in the use of data processing, it seems unlikely that the two can ever be totally separated. The instructing and directing of the end user, not to mention the care and maintenance of the systems themselves, will always be important functions of the DP professional. Data processing must look at each problem as a set of needs to be met. The function of the information center is to figure out how best to serve the user at the lowest cost. According to Benoit, "The information center is not meant to be a money maker — the main function is support." Most firms reported a positive acceptance from users and found

them very appreciative when the information center was able to adapt software to meet their needs. Of the many corporations now using the information center concept in hopes of alleviating backlogs, more work is needed to make the software easier to use. Even IBM, which pioneered the idea, seems to have a weak link in this area and has left much of the development to independent vendors. Comments from many firms indicated that IBM has given little assistance in this area, resulting in an expensive learning process for the information center. "IBM's technical support is severely lacking," one information center manager commented. In response to this inadequacy, the market for easy-to-use software seems to be growing considerably.

According to a 1982 study done by International Data Corp. (IDC) of Framingham, Mass., Mathematica Products Group, Inc., with its Ramis II package, was a leading seller. Mathematica's market share, based on U.S. independent software suppliers of nonprocedural DBMS-based packages, was 22%, compared with 18% for Information Builders with Focus and 12% for Infodata Systems, Inc. with Inquire. Competing with these three products is Nomad 2 by National CSS, Inc., which in the past, was only offered over its time-sharing network. National CSS would like the product to serve as the foundation of corporate information centers and has since announced that the product will be available as a stand-alone package to IBM's VM/CMS environment.

The National CSS staff intends to provide training to the in-house DP professional as well as to the consultant who will teach end users to access and manipulate the software. IDC expects the company to show significant revenues from the delivery of the repackaged Nomad 2 in 1983 and 1984. Cullinet Software, Inc. also is working on a product to be geared toward the information center concept. It plans to introduce its product sometime next year.

IDC predicted that there will be overall growth for all vendors in information center-oriented products, such as report writers, financial planning packages, spreadsheet packages query systems. It is estimated that the marketplace for these systems will exceed $83 million this year.

But Big Blue has not totally ignored plans for information center software and has a range of products available. For financial model building, IBM's "A Departmental Reporting System is highly used, as is SQL/DS — a relational query language for the IBM DOS/VSE environment. IBM's financial planning system APL is also popular. The problem with its products, according to many users, is that the information center user must learn a multitude of products. IBM is looking into the problem and has established a division for the sole purpose of reviewing all of the company's software, both existing and proposed. However, industry experts believe that it may be several years before any real progress is seen.

Impact of the Microcomputer

Firms are discovering that available microcomputer software is easier to use and learn than the typical information center software. Micros enable a user to control his functions more easily and helps him to become more relaxed with the DP aspects of business.

"Our information center would have taken off in a more traditional mode if the micros had not come onto the scene so strongly," Central Fidelity's Thomas said. He also found that given the choice, nine out of 10 information center users wanted micros. Because of these preferences, corporations are concurrently looking at personal computers for corporate use while developing their information centers. The cost of a personal computer is often equated with the price of an office copier, so when presented in that light, some firms are willing to go the personal computer route.

Many centers find that the major thrust into the micro arena has been an unexpected development because they were planning on using mostly mainframes. The microcomputer has had a tremendous psychological impact in raising the level of computer literacy.

Security with personal computers is not easy to control, therefore sometimes a personal computer may not be the answer. Applications have varying requirements. Some have to be done on mainframes because of security, for example, employee evaluations, while others, such as seating arrangements, can be performed on micros.

Firms are discovering that available microcomputer software is easier to use and learn than the typical information center software. Micros enable a user to control his functions more easily and helps him to become more relaxed with the DP aspects of business.

According to Benoit, "You have to look for where the problem really lies and remember that your goal is to solve that problem. At Fleet, we sometimes recommend a personal computer and other times the mainframe. I see our role at the information center evolving into an umbrella structure. We are the consultants overseeing both the personal computer and the mainframe environments."

Some centers rely exclusively on the mainframe and do not see the personal computer figuring into their networks at all, while a number of other centers have based their approaches on outside time-sharing services. The concensus seems to be that whatever fits well into corporate policy is the direction the information center will take. There seems to be little doubt in anyone's mind that there

will be more cross-pollination between the different options available to the information center

Directions

Where is the information center going? Clearly, today the information center is freely developing on its own, away from the original IBM model. Directors and staff of existing information centers are no longer dependent on IBM, and many who began with IBM have abandoned that structure. They now have the experience and knowledge to guide their organizations through the present multivendor environment.

Central Fidelity sees the information center as serving an interim function whose purpose will change once the interim phase has passed. This interim period will end once more computer literate employees come on board. "Today's youth has a far greater exposure of the use of computers as a tool than our present-day management," Thomas said. "They will bring into the corporation more education and skills by which they can use the computer for decision-making activities along with the traditional number-crunching functions." Thomas feels that once this transition period has ended, the information center will be a control center for managing the variety of software tools available to end-user departments.

Others see the information center as changing people's perception on how to do business and increasing the user's awareness of the tools available. But the information center will always be needed as an overhead support group. As the resources available to the information center are updated and expanded, the consultants can better advise and train users. The center may assume the role of a clearinghouse by offering up-to-date information on changing technologies.

Currently, there is a growing movement to link personal computers to mainframe data bases, which will greatly increase the need for the information center. As communications software becomes more powerful and sophisticated, more tools will be conveniently available to the end user. This will be just another way of bridging the gap between the traditional DP world and the business world.

The importance of the information center is directly linked to the importance of the executive's need for timely and understandable data. The sooner management receives the necessary information, the quicker business decisions can be made. The future success of any company will be determined by its ability to control and utilize large amounts of information, and if the information center can facilitate this, then the center is a success. It does not matter what shape or form the center takes; it only matters that it benefits the company. A combination of mainframe usage, microcomputer usage and time-sharing services seems to benefit the end user most since the proper tool can be used for each separate situation.

As one executive put it, "You can never learn how to drive a car if you are always being chauffeured. If you know how to drive the car, you have a say in where you go." The information center enables the user to have a say.□

Getting There From Here

By Naomi Karten

Blue Cross/Blue Shield of Massachusetts, located in Boston, has deliberately departed from IBM's emphatic guidelines that information center staff must never program for end users. The decision to be flexible about this matter has yielded a dimension of productivity beyond that of the "pure" Information Center as envisioned by IBM, while providing a more challenging environment for information center staff.

To establish an information center, IBM recommends selecting and implementing user-oriented products, providing access to data and training and supporting users. But do not, the guidelines advise, write code for users, for in so doing, users will become dependent on you. This advice has merit, however, rigidly adhering to it misses what is the most important reason for the existence of an information center — to allow users quick access to data, or, as the popular expression goes, to enhance productivity. The emphasis, in other words, ought to be more on the quick access and less on the means of achieving it.

When the information center was established here three years ago, the mission was pure IBM-ese: to provide end users from all corporate departments with tools and techniques to allow them to access their data on their own terms. We selected, acquired and installed mainframe and microcomputer products, set

ILLUSTRATION BY JON MARTORI

up training facilities and a hot line and established a walk in center for user access to each product.

However, management's need for information should not have to be put on hold while awaiting the next training class, the next software release or the reformatting of the next file. We discovered that all too often the user was not yet appropriately trained when information was required, that the logic of the request was complex and more quickly satisfied by programmers, that the data was not in a format suitable for user access or that the information need could not be satisfied by end-user software, but was amenable to conventional programming techniques.

We were able to learn about the location and use of much of our corporate data. In pre-information-center days, ad hoc requests requiring data from both the IBM and Honeywell data bases often resulted in two or more DP departments dividing up the responsibility.

As a result of these observations, we resolved to take seriously the term "information center" — that is, literally to be a center for information. Our department name — Information Central — reflects this philosophy. Three basic objectives drive the center:

- To acquire and install end-user products, provide access to data and train and support users.
- To develop technical solutions to ad hoc requests for information, using the full range of installed software.
- To develop and make available general-purpose solutions to the common business needs of multiple user areas.

With the first of these objectives, our experiences have mirrored those of many other companies. The second and third objectives, however, have led to some interesting insights about the benefits of our approach to both users and DP.

One of the first realizations was that two categories of software products are suitable to an information center environment: those that are paid for, acquired and installed specifically for the center and those that are free of charge insofar as the installation already has them. The free-of-charge category for Blue Cross Blue Shield of Massachusetts includes Syncsort, Inc.'s Syncsort and IBM's TSO command language Clist on our IBM mainframe and Honeywell, Inc.'s database language, IDS/Cobol, on our Honeywell mainframe.

In addition to its sort capabilities, Syncsort provides parameter-driven record selection, manipulation, formatting and reporting capabilities. Since so many file queries are logically simple ("Get me a list in certificate number sequence of all first-quarter claims between $100 and $1,000, excluding maternity claims"), Syncsort has been an ideal tool for use by information center staff. Furthermore, although Syncsort might not qualify as user-friendly, many users are capable of learning many of its parameters.

Clist-Based Systems

Though too technical for non-DP users, Clist has facilitated development of small systems and subsystems extremely quickly. A sampling of Clist-based systems we have developed includes:

- A series of data entry screens and data edits to support a planning department's collection of handwritten medical review data. It takes less than one day per person to develop, and the benefits include user-controlled, error-free data entry.
- A Job Control Language generator, which queries for and validates such things as accounting information, file names and whether the data is to be sorted. It takes one week to develop, and the benefits include customized, error-free Job Control Language for use with user (or programmer) code.

The policy of the center is never to write Cobol code if a faster alternative will do the trick. We have, however, built up a good-size library of Honeywell IDS/Cobol programs to extract data from our major Honeywell data bases. Whenever possible, we produce reports from such data bases by passing the data to a report generator. As an example, a frequent user need is to analyze data residing partly on the Honeywell mainframe and partly on the IBM mainframe. We are very impressed with the file manipulation capabilities of SAS Institute, Inc.'s Statistical Analysis System (SAS) and frequently do a Honeywell Cobol extract, a data transfer to IBM, a Syncsort extract of the IBM-resident data and an SAS file merge, analysis and report.

SAS code is written in-house whenever it is the most expeditious way to complete a user request. SAS is not only a tool to support users; we have developed SAS data analysis and debugging routines for use by other DP areas.

As a result of these programming activities, we have become more conversant with users' information needs than if we simply taught them a language and supported them. In addition, we became aware of the overlapping needs among departments, which was especially useful, for individual departments were not aware of this overlap. By coordinating all ad hoc requests, we are in a position to explain to users that, for instance, they can obtain the needed information from a report already generated in another department or we are already preparing a similar report and will run off an additional copy for them.

Frequently, we generate an extra copy or two of a report, knowing that eventually another user will ask for the same information. Not surprisingly, users frequently accept reports today that meet most of their needs rather than wait several weeks or months for

reports that are 100% to specifications.

In supporting so many areas, we were able to learn about the location and use of much of our corporate data. In pre-information center days, ad hoc requests requiring data from both the IBM and Honeywell data bases often resulted in two or more DP departments dividing up the responsibility. Working with data from multiple and diverse sources has enabled us to become knowledgeable about these sources.

Personal Computer Support

Another way we have been able to support users is in personal computer work. One of the responsibilities of our information center is to provide end users with microcomputer training and support, as well as assistance with configuration analysis, acquisition, installation and software evaluation. These activities offer many opportunities to become aware of common business problems that are amenable to generalized solutions. We have developed several Visicorp Visicalc models that we documented for general distribution and demonstrated on demand. For 1984 budget preparations, we developed Visicalc spreadsheets to accommodate the needs of budget representatives from each major functional organization within the company.

By coordinating ad hoc requests, assessing overlapping needs and developing technical solutions, users receive information more quickly while DP benefits by the elimination of redundant and resource-consuming programming efforts.

As with any information center, patience, an outgoing personality and a strong service orientation are key requisites for staff members. Familiarity with business functions through experience in a user area is an important plus.

Although information center staff are technically trained, they do not need an extensive DP background. In fact, given one or two experienced programmers with supervisory capabilities, this environment is ideal for entry-level or junior-level programmers. In the past 2½ years, seven programmers have joined the department with DP training but little or no DP experience.

Although we have done little formal marketing of our services, word of mouth has worked well, and we have a continuous influx of requests. The result is a constant juggling of the work load in such a way as to please most of our users most of the time and still give immediate attention to numerous high-priority requests.

Given the scope and variety of the services provided by Information Central, it appears our approach has turned out to be a wise decision:

- With our end-user products, we are supporting a solid base of users capable of "doing it themselves," and we are continually assisting new users to become conversant with these products.
- By doing both training and programming, we have gained a broader sense of corporate objectives and business needs than many other DP and non-DP departments have.
- To respond to requests from all areas, we have developed a greater familiarity with our corporate data than many other DP departments have.
- To respond to user requests as quickly as possible, we have acquired a broader range of technical skills than many DP departments, and a bigger "bag of tricks" than most DP departments.
- By building a library of general-purpose and specialized solutions to business needs, we can support the greatest number of needs with the least amount of effort on the part of users, the rest of DP and ourselves.

In all probability, if we had put all our resources into the straight and narrow approach, we would have many more end users up to speed in preparing and running their own code. But by incorporating programming among our information center tools and techniques, we have been able to contribute much more to the overall efficiency of information usage within the corporation.

The Time Is Now

By Stephen L. Samson

With the second release of MVS/Extended Architecture (MVS/XA) now available, IBM has provided real improvements in performance, configurability, reliability, availability and serviceability, as well as additional function and device support. What these improvements add up to is strong motivation for converting MVS/370 systems to MVS/XA, if the XA hardware is already in place.

The latest MVS/XA release is the combination of MVS/SP Version 2, Release 1.1 (MVS/SP 2.1.1) along with the MVS/XA Data Facility Product (DFP), Release 1.1. It runs only on a CPU complex that provides the System/370 XA mode of operation. Processors capable of operating in this mode include all of the IBM 3080 systems: the 3083 uniprocessor, the 3081 dyadic and the 3084 dual dyadic. The IBM 4381 announced in mid-September can operate in XA mode as well.

MVS/XA is IBM's vehicle for delivering new functions at the high end of its product range, now and in the future. Many of the innovations in MVS/XA, such as the dynamic channel subsystem and enlarged virtual storage size, are useful at the low end as well and have been incorporated in the new 4381.

Based on experiential data now available from users, MVS/XA has been easy to install, and operating it comes easily to an MVS operations staff.

Previously, MVS/XA was hard to install on a production system and did not offer major performance improvements other than with

3380s and Dynamic Path Reconnect. It needed more real storage and provided no functional benefits other than the ability to use 31-bit addressing for applications programs and support for the 3084. Moreover, while providing some virtual storage constraint relief of 1.3M to 1.6M bytes below the 16M bytes "line," MVS/XA's larger control structures and added functions demanded 4M to 8M bytes of real storage beyond that required by MVS/SP 1.3.

As of Sept. 1, the second release of MVS/XA includes:

- A simplified installation procedure using IBM's System Modification Program-Extended (SMP/E) program, which eliminates the need for a full Sysgen (and subsequent reinstallation of other programs) to install MVS/XA.
- Support for the 3880 Models 11 and 13.
- Virtual storage constraint relief beyond Release 1 in both the base control program and in DFP of 400K to 600K bytes.
- Support for the MVS/SP 1.3.3 version of JES2.
- Global Resource Serialization support of Vsam data set sharing.
- Linklist enhancements for performance, integrity and operational flexibility. The limit of 16 data sets in the LNKLST concatenation is removed, and unauthorized libraries may be in the concatenation and optionally may remain unauthorized in use. (The two previous features provide the means to eliminate Joblibs and Steplibs in many applications jobstreams.)
- Introduction of a Linklist lookaside address space to contain the composite Linklist library directory, along with improved search algorithms and control and updating facilities. This eliminates the need for tuning to resolve conflicts between the management benefits of logically grouping modules in separate libraries on the one hand, and the poor performance of searching through concatenated directories on the other hand. There will be reduced need for extensions and modifications to the BLDL function.
- Generalization and increased flexibility by allowing SYS1.LOGREC to reside elsewhere than on the IPL volume, by supporting concatenated LPALIBs, and by supporting an arbitrary suffix for the IEAPAK member of SYS1.PARMLIB. These changes eliminate the binding of an IPL volume to a single system and, thus, make possible the sharing of IPL volumes across multiple systems.
- Vsam restructuring, including record management code above 16M bytes, I/O buffers also above the line, and up to 16 local shared resource pools per address space. The pools can reside above the line.
- Residence above 16M bytes of I/O buffers for virtual I/O (VIO) data sets.
- Availability enhancements, including a separate address space for System Management Facility (SMF) and the ability to restart SMF after a failure.
- Serviceability enhancements, including the ability to suppress duplicate dumps.

There are many more detail-oriented changes in this release; the IBM announcement materials provide complete information.

A flippant answer to the question "When should you go to MVS/XA?" might be "As soon as you're ready." Given hardware that supports XA and an MVS environment, including the proper "positioning" releases and products as defined by IBM, the only reason to delay installing XA is an inadequate or unsupported element in the hardware configuration. MVS/XA requires more real storage than does MVS/370. If a system is storage constrained in MVS/370, it will be very storage constrained in XA.

Installation of MVS/XA, in all but very unstressed real storage environments, should be accompanied by an additional increment of main memory. The increment for the 4381 is 4M bytes or 8M bytes; 8M bytes is the only increment available for 3080 systems. Along with the 4381 announcement, IBM made available two new real storage sizes for the 3083 Model E (24M and 32M bytes) so a model upgrade is no longer needed if a 16M-byte 3083 Model E is to perform well under MVS/XA.

Unsupported devices include 2311 and 2314 disk storage devices and the 2305 Model 1 fixed-head file. IBM has been dropping support for these devices over time; the 2311 was not supported in MVS at all, and in MVS/XA, they are not even supported as virtual devices to set the formats of VI/O data sets.

Along with the initial announcement of MVS/XA, IBM introduced the notion of "positioning" — releases of MVS/SP 1.3 and key program products that, if installed before conversion to MVS/XA, permit near-transparent migration. The concept works and can be accomplished without unusual effort. On the other hand, MVS shops converting to XA from a level of MVS lower than SP 1.3 must assimilate a tremendous amount of change, most of it arising from the functions that were new in 1.3.

The ideal move is from a 3080 running SP 1.3.X and an SP level of JES2 or JES3, with some currently unused real storage and no system modifications. A carefully drawn migration plan would include the preliminary steps necessary to achieve this configuration while acquiring whatever MVS/XA training that might be needed.

Non-IBM software, such as library management systems, data base and data communications subsystems and performance monitors, which work on MVS/370 but not on XA, may impose a delay on migration or leave the XA system less useful than the 370 system. Users should consult their vendors well in advance of conversion to XA to ensure timely support. Some independent vendors have announced MVS/XA support for all applicable products.□

Unraveling The Mysteries Of Micro Operating Systems

By Jeff Fox

Just as the number of microcomputers on the market keeps increasing, so do the number of operating systems that are available for these computers. A user today is confronted with a choice among many computers offering different operating systems and features.

An operating system is the program that actually runs the hardware of a computer. In the earliest microcomputers, the operating system consisted of 1K byte or less of code on read-only memory (ROM). The most primitive of these systems would require the operator to toggle in a boot program on front panel switches whenever the computer was powered up.

The second generation of operating systems included a boot program on ROM with keyboard input and video output and, perhaps, cassette or paper tape mass storage. The third generation of operating systems provided mass storage on a floppy disk. These operating systems usually defaulted to a version of Basic in ROM; in some cases, the operating systems

were hidden in Basic.

Early microcomputer disk operating systems offered the most primitive commands. Initialize a disk, Read/Write a File, Catalog the files on a disk; Rename a file, and so forth. Each vendor offered its own unique disk operating system and standards evolved only when more than one manufacturer offered the same operating system on their computers.

There were two advantages to offering a standard operating system to the user. If users were already familiar with the features of a given operating system, they would be able to use the machine more quickly. Also, programs could be transportable to any computer that could run the operating system in which the program was written.

After a decade of growth, microcomputers have become very sophisticated. There are usually a number of different operating systems available for a specific microcomputer. The features offered by these systems are quite varied and should be examined individually.

Most, but not all, microcomputer operating systems support file I/O. At the command level, operating systems will recognize and respond to specific instructions to create files, load files, erase files, copy files and so forth. These same functions can be accessed by programs running under a given operating system through calls to specific locations within the operating system.

Through the use of compatible file structures, data stored by one program may be accessible from another program under the same operating system. It is also possible for an application program to read a file written under a different operating system if it was written with compatible hardware and all of the rules for the structure of the file were coded into the application.

This can be a very involved process, and most users must exchange data stored under different file structures with special conversion utility programs. Many of these types of utility tools are available; but if buyers anticipate performing conversions, they should check to see that vendors offer such conversion aids.

Concurrency

Concurrency, a form of multitasking, is the execution of more than one program at a given time in a computer. To do this, the operating system must switch between program tasks very rapidly. The controlling program in the operating system functions as the controlling task and coordinates the operation of other tasks. Multitasking operating systems do not all have the same features. The size or number of tasks vary from system to system, and the mechanisms by which tasks communicate with one another or the user also vary greatly.

The most simple implementation of multitasking may be a simple background print spooler. More sophisticated multitasking systems allow tasks to create, schedule and dispatch other tasks. In the most sophisticated operating systems there are numerous mechanisms to control the interaction of tasks. In these systems, tasks may be assigned priorities and may dynamically modify the priority status of other tasks.

The trend in microcomputer operating systems today is to offer multitasking capability, which expands the power of the system. Concurrent CP/M 86, for example, is an expansion of Digital Research, Inc.'s CP/M-86. Based on the enthusiasm surrounding the introduction of Apple Computer, Inc.'s Lisa, many vendors will try to offer multitasking with a window display so that users can interact with the system to perform more than one task at a time.

Multiuser operating systems are multitasking to switch control of the system between more than one user. In these systems, each user must be restricted from interfering with the operations of other users. Even for a single multiuser operating system the number of users will vary according to implementations and hardware configurations.

Every operating system has minimal requirements for its operation. These requirements may be broken down into memory requirements, mass storage requirements and I/O requirements.

The most primitive microcomputer operating systems need only a single ROM chip and very little random access memory (RAM). Today's standard operating systems usually require a minimum of between 32K bytes and several hundred thousand bytes of RAM.

The trend in microcomputer operating systems today is to offer multitasking capability, which expands the power of the system. Concurrent CP/M 86, for example, is an expansion of Digital Research, Inc.'s CP/M-86.

Implementations vary in their use of memory, and the size of the operating system may be an important factor. If the operating system uses a large amount of the memory of a small microcomputer, there will be very little left for application programs and even less for their data.

Multitasking operating systems require not only sufficient memory space for each task, but also some form of memory management. This means that the memory must use a bank swapping mechanism or some form of logical vs. physical addressing. Without such a mechanism, an operating system would have to copy sections of memory byte by byte to be able to switch tasks. Most of the newer 16-bit micros have sophisticated memory management segment control built into the hardware.

The first requirement of a mass storage system is sufficient space to store the operating system itself. For this reason, some of the micro-

computer operating systems require a hard disk because floppy disks are simply not large enough.

For multitasking systems that need more memory than the system contains, there is a second requirement of mass storage. It must be fast enough to support virtual memory. Virtual memory is the technique of swapping sections of memory to and from mass storage in such a way as to simulate a larger memory space.

Not all multitasking systems use virtual memory, and not all operating systems that support virtual memory are multitasking. Virtual memory can be implemented on a floppy disk, but since speed is very important, virtual memory will usually require a hard disk.

Many large software houses are gambling that Unix will become an industry standard for microcomputers. They are investing large amounts of money to develop new versions of Unix to test this hypothesis.

I/O Requirements

The computer system selected may need minimal I/O functions in order to support a given operating system. There are several possible I/O restrictions.

Text output may require certain abilities such as a minimal number of characters per line, upper- and lowercase characters or character attributes such as blinking, bold and others. Text input may also require that certain characters or special keys be available from the keyboard.

Some operating systems make heavy use of graphics and will need specific graphics devices to operate. These systems require a high-resolution, bit-mapped graphics device for all output, text or graphics. This is because in an operating system such as Xerox Corp.'s Smalltalk, all text output is actually done in graphics.

Serial I/O may be supported through a particular type of hardware under a given operating system. Various synchronous and asynchronous communications protocols may be supported. Certain systems require serial ports — for example, in a multiuser system each user may be attached on a serial line.

Some special devices may be supported by operating systems. In particular, Smalltalk relies heavily on an input device called a mouse. The mouse is similar to a video game track ball. It is used to position a control cursor on the screen. Other devices that may be supported are light pens, touch screens and digitizing pads, among others.

Finally, some operating systems provide networking support. They allow more than one computer on the network to share resources. The interconnection of computers on the network will require a specific type of networking hardware. These can range from simple asynchronous communications links to very high-speed coaxial cable or light link.

Operating Systems Survey

CP/M from Digital Research was the first really popular standard operating system. CP/M stands for Command Program for Microprocessors. It was initially developed for the 8-bit Intel Corp. 8080 and the Zilog, Inc. Z80 family of microprocessors; later, it was written for the 16-bit 8086 family.

The greatest advantage that this operating system has over most others is the large amount of CP/M programs and literature available. CP/M versions have different memory requirements but some can run in as little as 32K bytes. This operating system will allow redirection of I/O to devices or files.

Concurrent CP/M is an operating system that allows more than one CP/M program to run simultaneously. This system offers the multitasking abilities of larger, more complex operating systems with the large base of programs available in CP/M. Digital Research's MP/M is similar to CP/M 86 and Concurrent CP/M 86, but in addition to the features they offer it has multiuser capabilities.

Microsoft, Inc.'s MS-DOS, also known as PC-DOS on the IBM Personal Computer, is a single-user operating system with many similarities to CP/M and CP/M 86. MS-DOS has become the most common operating system for systems with the 8086 and 8088 families of microprocessors. The range of products available for MS-DOS is already very large and still growing, and MS-DOS will support simple background print spooling. At least one manufacturer will soon offer a multitasking version of MS-DOS.

UCSD Pascal is nearly as popular as MS-DOS. This operating system was developed at the University of California at San Diego and features a very powerful version of the Pascal language. It is not limited to the Pascal language, however, and a very large number of programs are available for UCSD Pascal.

Unix is an operating system that was developed at Bell Laboratories for the Digital Equipment Corp. PDP-11 minicomputers and was then written for the Motorola, Inc. 68000 microprocessor. There has been a great deal of attention given to this operating system recently, with many vendors rushing to provide new versions of Unix for other microprocessors.

The new stripped-down versions of Unix that are available differ somewhat in their features. Generally, Unix is a multitasking, multiuser operating system with some very powerful features. I/O can easily be redirected to or from devices or files, and pipes can direct data from one program or task to another.

Unix has been very popular in the academic community. As university graduates have moved into industry, they have taken their preference for this operating sys-

tem with them. Unix offers some very powerful utilities, including output to phototypesetting and document complexity analysis.

The disadvantages to running Unix have been the high cost of purchasing versions of this operating system and the high cost of the minimal hardware requirements. Now that Winchester disks and dynamic RAM costs have lowered the cost of the minimal hardware needed for Unix, vendors are able to deliver lower cost versions of the system.

Many large software houses are gambling that Unix will become an industry standard for microcomputers. They are investing large amounts of money to develop new versions of Unix to test this hypothesis.

Xenix, from Microsoft, is very similar to Unix except that it has been developed specifically for microcomputers. It is currently available for the Zilog Z8000 and will soon be available for the 8086 and 8088.

Smalltalk is a language and operating system developed at Xerox. This operating system has been available on the Xerox Alto and will soon be available on Apple's Lisa. The Lisa comes with its own proprietary operating system, which offers many of the features of Smalltalk. This object-oriented language requires a bit-mapped graphics output and a mouse for input and a good deal of mass storage and memory. It will allow the development of programs that use its unique methods for user interaction.

Smalltalk has influenced vendors to offer some of the features developed in Smalltalk in packages for other operating systems. One of the most interesting is the use of windows for program output. The output screen is divided into sections called windows by the operating system, and multiple tasks can communicate with the user simultaneously through their own windows.

Forth, from Forth, Inc., is a language and operating system that is available for virtually all microcomputers. There are so many versions of Forth that it can cover a very wide range of power and cost. The smallest version of the system will run in under 8K bytes of memory, and yet may offer an interpreter, a compiler, an editor and even an assembler resident in the operating system. Large versions include the ability to compile applications for a completely different target computer system.

One advantage to this operating system is that, because it is in the public domain, the source code is available. For some systems it is possible to get a version of Forth with an editor, assembler, source code and a meta compiler to compile new Forth systems all for the cost of a diskette.

Each of the microprocessor vendors offers various operating systems for the hardware configurations they sell. For each manufacturer there is usually a range of operating systems available that will offer more or less features. Since these operating systems are not available on other brands of computers, they will not become standards unless they are very popular in the user community and other manufacturers purchase the rights to these operating systems and make them available on other systems.

One of the more interesting recent developments in operating systems has been the silicon operating systems. These are operating systems that have the required hardware (interrupt controllers and memory management chips) integrated with the operating system software into special chips. This approach reduces chip count and produces faster, more standardized systems. Many manufacturers are offering these silicon operating systems.

Intel's 80186 and 80286 systems provide multitasking with more power and fewer chips than systems based on the 8086 or 8088. Intel also has the 432 chip series, which offers a multitasking, multiple-CPU operating system in microcode rather than in ROM.

Despite new developments in operating systems, users must examine their application needs and select operating systems that run those applications. If the user has already purchased microcomputer hardware, then he is generally limited to purchasing only those applications packages that will run on the operating system he has chosen.□

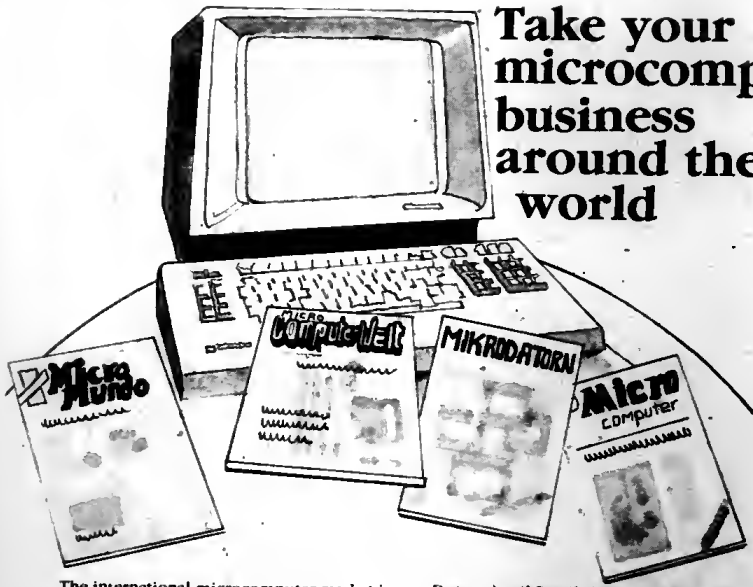
Take your microcomputer business around the world



The international microcomputer market is booming. An annual growth rate of 40% is forecast through the end of the 1980's. Countries that are recognizing the need to computerize their governments, industries, and universities are looking to low-cost micro computers, thus creating worldwide opportunities. Microcomputers are affordable, adaptable and efficient. And the supply cannot satisfy the demand.

Computerworld's international network of publications has the microcomputer market covered. We'll put you in touch with microcomputer buyers around the world through the special micro sections or monthly inserts in one or more of our 30 publications in 24 countries.

And we now publish separate monthly magazines for the microcomputer users in Australia *(MicroWorld)*, West Germany *(MicroComputerwelt)*, Sweden *(Mikro-Datorn)* and Brazil *(MicroMundo)*. Reporting the latest products and treods, these monthly magazines talk to the microcomputer buyers and users in these markets — in their own language — with locally edited news and international developments.

If you're marketing plans include the international market, the time to act is now. Micros are the fastest growing segment of the computer industry. Whether you want to test the market or are looking for a distributor or representative, we'll put you in touch with the right people around the micro world.

15 pointed questions to ask MSA or any software supplier

1. Can you offer us a complete range of application software systems designed to work together?
Or will we have to piece together a patchwork of systems?

2. Can you link our personal computers directly to our mainframe—so managers can get their own information?
Is that software available right now?

3. Are your systems just record keepers, or can they really help us make decisions?
Can we pull together information from any of our integrated systems? In exactly the form we want it?

4. Can you provide business software for both mainframe and microcomputers?
Do you develop this software yourself or do you simply market it for another company?

5. Are your systems truly online—so all of our information is current?
How many of your systems are online? How secure are they?

6. Will my company have to be the one that discovers the bugs in your brand new system?
Just how long have your systems actually been used and how have they been tested?

7. Will you update your systems as technology advances and regulations change?
What are some of your most recent updates? Will you keep us current on regulatory changes?

8. Do your systems really do everything you say they will?
Or will we have to change them or add to them to get the features we want?

9. How long have you been in business? What are your revenues? What is your growth record? Where will your company be five years from now?

10. How many systems has your company installed?
How many of these were installed in the past six months? How many of your earlier customers are still using—and liking—your systems?

11. Do your financial systems handle unlimited foreign currencies?
Do your financial systems use a common set of currency exchange rates?

12. How will you make sure my people thoroughly understand your system?
Do you have educational centers near us or will we have to travel all the way across the country to find one? Will you be there to help during installation and after?

13. How many of your people specialize in software for my industry?
How many accountants work for you? Human resource specialists? Manufacturing experts?

14. Do your systems have built-in features that make them easier to use?
What happens if someone needs help figuring out a feature? Do you have online documentation that's easy to understand?

15. As my business changes will your system be flexible enough to change with it?
Or will I have to pay a lot to revamp it? Or even regenerate it?

If you're confused about buying software, arm yourself with these questions. They can help you make an intelligent software decision. And if you'd like to know more about software, talk to MSA. We can show you how to put together a total mainframe and microcomputer system that will solve your present problems, and take you into the future.

Now you've got the questions. Turn the page and get the best answers.

15 candid answers from MSA

1. MSA offers the most complete line of totally integrated systems in the software industry, including financial, human resource, manufacturing, and mainframe/micro products. So you avoid the headache of trying to tie together individual systems.

2. MSA's new Executive Peachpak II™ software can link your company's personal computers to your mainframe, so you can get to vital information without waiting for print-outs from data processing. It's available from MSA right now. (In fact, it's already up and running.)

3. MSA systems are decision support systems that pull the right information together in a form meaningful to the user. Flexible report writers and screen generators let you get at information quickly and easily.

4. MSA acquired Peachtree Software in 1981 and became the first and only vendor to offer a full line of software for both mainframe and microcomputers. We've planned our growth and the growth of our products, developing each system to work with the others.

5. All MSA systems are online and provide security for the user's database above and beyond typical online systems.

6. Our systems go through a stringent series of in-house tests by a quality control team, then they're tested by several customers before being released to our customer base. Thousands of successful installations prove MSA reliability.

7. MSA maintenance includes keeping your system up to date technologically. Enhancing it with new features. And making sure it reflects changes in accounting procedures and government regulations, including 401(k), TEFRA, and FAS52.

8. Our approach to software allows customers to define systems to meet their needs without modifications or customization. Ask any of thousands of satisfied customers.

9. MSA is the largest independent supplier of application software, with 1982 revenues of more than $100 million. Our growth rate has exceeded 45% annually over the last 10 years.

10. MSA's customer base exceeds 5,000 companies and 8,000 software packages. Customers on our maintenance program still have state-of-the-art software—and many have been MSA customers for more than 10 years.

Here are just a few of the big names who keep coming back for more HASP+.
B.F. Goodrich, Caterpillar, Fairchild, Lockheed, Martin Marietta, McDonnell Douglas, Xerox, Hughes Aircraft, Signetics, British Aerospace, U.S. Army.
Like them you can depend upon the 12 years experience built into

DEC HASP HASP+™
The Missing Link.

PDP-11/VAX Interconnect to IBM, CDC, DEC, and most others

HASP+ is highly versatile. Can operate as a host or remote work station, supports auto-dial, and much more. HASP+ uses standard DEC communications hardware

No-risk trial, direct technical support, plus low prices. VAX single systems, $5,500; 15 systems $2,500 each. PDP-11 prices slightly lower.

CONSCO

Fast, accurate, fully automated consolidations from CONSCO

We're the only people who do consolidations the right way. In fact, that's been our specialty for more than a decade.

Since our System is dedicated to consolidations, you can expect a lot more from it. Your accountants will be freed from the tedious tasks to do the more important things. And your management will get powerful, useful reports that just weren't possible before.

Our system provides

- **automatic reconciliation and elimination of intercompany balances.**
- **multiple hierarchies (geographic, legal, etc.) including lower level consolidations (by groups, divisions, and so on).**
- **changes to hierarchies without reprogramming or restating past data.**
- **automatic creation of journal entries (tax, minority interest, etc.).**
- **no limit on the number of periods or kinds of data, including budgets, plans, and forecasts.**
- **currency conversion and planning using average, current, and historic rates in conformance with FASB 8 or 52.**
- **fast reports that allow multiple formats on a single page, ranking of any data, and preparation of analyses and operating statistics and schedules required by management, the SEC, and the IRS.**

The Consolidation System has interfaced with practically all the major General Ledger packages, as well as our customers' in-house systems. Of course, it also interfaces pretty neatly with our own Accounting Information System.

Beyond the General Ledger

The CONSCO Accounting Information System (AIS), using relational architecture, brings all your data together so you can get the reports and analyses you need to run your business. CONSCO specializes in the tough jobs. Even if your requirements are so complex you thought you had to have custom software, AIS can handle your needs at packaged software prices.

Features of the Accounting Information System include the following:

- **all normal General Ledger and Subsidiary Ledger functions: accruals and reversals, standard entries, comprehensive allocation capability, detail analysis, and financial statements.**
- **absolutely no restriction on number of fields or field sizes.**
- **processing abilities are not limited to General Ledger data. Any number of subsystem and descriptive fields may be used for complete information processing.**
- **edit tables which incorporate full Boolean Logic. These tables may be changed at any time and may access any data field, hierarchical or otherwise.**
- **an unlimited number of budgets, revisions, projections, and statistics without the need for special account codes.**
- **unlimited time period history with the most efficient data storage organization.**
- **an extremely powerful Report Writer lets you use any data, even subledger and operations data, to create the reports your people need.**
- **full on-line capabilities for data entry, update, and inquiry.**

CONSCO's commitment to you does not end with our software. We offer on-site training and support, and our customers have formed a Users' Group.

Our customers include many of the largest companies in America (a customer list is available upon request).

If you're a complex, large organization, or if you have difficult problems that need mainframe software which goes beyond a mere General Ledger System, call or write CONSCO for more information.

Learn more about Personal Computing, Office Automation or Communications in these video journals from CW Communications and Deltak.

Personal Computing: A Business Perspective
Taped on location during CW Communications' COMPUTERWEEK conference, these six video sessions feature many of the biggest names in the microcomputer industry as they share their insights into the application of personal computers in the business environment. Each of the six tapes is 20-30 minutes long, and focuses on a specific issue. Available through Deltak singly or as a group.

- *Thinking Small for Big Business*
- *The Purchase Decision*
- *Finding a Vendor*
- *Sales Trends and IBM*
- *New Languages and Networking*
- *A Look Toward the Future*

Office Automation: The Essential Issues
Last Fall, executives from around the country attended the OA Forum, a national conference conducted by CW Communications on the introduction, integration and implementation of office automation in today's business environment. Leading industry experts and top corporate managers discussed key office automation planning issues. These discussions are now available to you in seven carefully edited conference journals. Each journal is in full color, and 20-30 minutes long. They are available from Deltak singly or in a group.

- *The DP Role in Office Automation*
- *Planning for Office Automation*
- *The Fundamentals of Integration*
- *Some Specifics of Integration*
- *The Executive Workstation*
- *One Company's Experience*
- *Introducing Office Automation to Your Organization*

Communications
Leading experts in all areas of communications were recently taped at the 1983 Communication Networks Conference in New Orleans. The result was two brand new video conference journals of key interest to all levels of corporate and technical understanding:

- Communication Networks: Alternatives for the 80's
- Local Area Networks: The major considerations

All of these useful journals are available through Deltak, inc., 1751 Diehl Road, Naperville, IL 60566. To get more information, or to find out about rentals, just call Deltak Order-Entry at (312) 369-3000 (in Canada, (416) 678-9222), or check the white pages of your telephone directory for the Deltak office nearest you.

NEW
REALTIME ACCOUNTING CONTROL

NO OTHER GENERAL LEDGER MEASURES UP

We've just enhanced the industry standard, and we're confident it's the most advanced general ledger on the market.

Selective Realtime ability provides precise feedback from your general ledger. Immediately. Realtime maximizes the efficiency of your accounting operations.

Comprehensive system security and audit controls are built into the system to ensure data integrity. You control who can enter, review and make changes to your financial information. Audit trails allow you to trace the source of transactions.

Our Variable Report Writer lets you design, maintain and control every report that comes out of your system. The automatic building of reporting structures allows you to rapidly address your company's reporting requirements. An extensive standard format library eliminates the need to design basic financial reports. You can also use a common format across reporting entities. No other general ledger provides as much easy-to-use reporting power and online access to information.

With our powerful online inquiry ability, you can query your financial database at a summary or detail level to immediately trace the source of a variance or an account balance.

Our package design accommodates your chart of accounts, not vice versa. You can design any account numbering system, up to a 24 alphanumeric free-format account number.

Sophisticated system architecture provides benefits not found in any competitive product. Detail and summary financial information is as accurate and up-to-date as the last physical posting to the system. System design can automatically reflect corporate changes and reorganizations in company reports.

Software International has been installing and supporting high quality financial application packages for almost two decades. Currently, our General Ledger and Financial Reporting System is hard at work for more than 4,000 of the best run businesses in the world—firms like E.I. Dupont, R.J. Reynolds and Miller Brewing. Hundreds of Fortune 500 Companies have selected our General Ledger over the competition's. As a wholly-owned subsidiary of General Electric Information Services Company, we are part of a worldwide family of more than 5,000 computer and business professionals.

For more information, call us today. Or write our Corporate Headquarters at One Tech Drive, Andover, MA 01810. When you take a closer look, you'll see that no other general ledger measures up to ours. We're continually improving our product to stay at the leading edge of software technology, and to serve the changing needs of the business world.

After all, you don't remain the industry standard by standing still.
